In the Korean war the predominant weapon on planes of the United Nations was the calibre .50 aircraft gun. To meet the challenge of supersonic jet planes, aircraft guns firing at the rate of several thousand rounds per minute were reported to be under development. The Russian MIG–15 planes were armed with a variety of larger-calibre, slower-firing weapons ranging in size from the calibre .50 to the 37-mm., including a 23-mm. gun with a cyclic rate of 700–800 rounds per minute. Many factors, particularly rate of fire and weight of gun and ammunition, are considered in assessing the relative value of small and large aircraft weapons.

Artillery.—As noted earlier, artillery weapons are classified according to barrel lengths as guns, howitzers or mortars, although the lines between the three types are not sharply drawn. World War I witnessed the development of a variety of light mortars, and weapons of this type saw much service in World War II and in Korea. Most infantry mortars have smooth bores and fire fin-stabilized projectiles, but the 4.2-in. United States mortar has a rifled bore. Because of their high angle of fire, mortars are used to reach targets behind hills or to lob projectiles into trenches. Broadly speaking, both mortars and howitzers are lighter and more easily manoeuvred than are guns.

Large permanent gun installations such as those in the Maginot line or in coastal defense batteries became outmoded during World War II, for they could too easily be attacked by aeroplanes or by-passed by mobile ground forces. In a war of rapid move-

ment, mobility became a prime consideration, and the older wooden-wheeled, horse-drawn field artillery weapons were redesigned and fitted with rubber tires, to be towed by trucks or tractors. To cope with heavily armoured tanks mounting powerful guns, all major powers developed special anti-tank guns (ranging upward from the 37-mm.) and self-propelled artillery. As the German 88-mm. anti-aircraft gun had been used as an anti-tank weapon dealing punishing blows to U.S. and British tanks in North Africa, a 90-mm. high-velocity gun to match the dreaded 88-mm. was put into service by the U.S. army. British and U.S. troops in North Africa also used a 105-mm. howitzer motor carriage nicknamed the "Priest" from its pulpitlike appearance. Larger gun motor carriages mount 3-in. and 90-mm. guns.

The field artillery of the U.S. army includes the 75-mm. pack howitzer specially designed for easy transport by pack animals; this weapon can be dropped by parachute from aeroplanes either assembled or unassembled. The 105-mm. howitzer is so widely used that it earned the title of "work horse" of the U.S. army. Mounted on a two-wheeled carriage, it can be towed by a truck or tractor or dropped by parachute from an aeroplane. The 155-mm. howitzer and the 155-mm. gun ("Long Tom") are used on towed mounts or on motor carriages. In the heavy artillery class are guns and howitzers of 8-in. (203-mm.) and 240-mm. sizes. The 8-in. gun fires a somewhat lighter shell as far as 20 mi. The mortars used by the U.S. army in the 1950s were the 60-mm., 81-mm., 105-mm., 155-mm. and 4.2-in. During World War II a 914-mm. ($36\frac{1}{4}$-in.) mortar known as "Little David" was developed but not used in combat.

German artillery in World War II included a similar range of weapons, from the 75-mm. mountain howitzer to the 540-mm. mortar used against Stalingrad. The most famous was the 88-mm. triple-threat gun that could be used against aircraft, tanks or ground troops. To achieve high velocity in anti-tank guns the Germans developed several tapered-bore weapons such as the 28/20-mm., 42/28-mm. and 75/55-mm., but they were not notably successful. Modern Russian artillery ranges from the 76-mm. mountain howitzer and the 76-mm. self-propelled gun to two huge howitzers of 280-mm. and 305-mm. bore. In addition to light and medium mortars the Soviets also employ heavy mortars ranging from the 107-mm. mountain mortar up to the 160-mm. Russian artillery pieces lack the refinements found in British-U.S. weapons, but they are rugged, simply constructed and very effective. The artillery used by the Chinese Communist army in Korea was a mixture of weapons made in China or the Soviet Union and weapons captured from the Japanese, the Chinese Nationalists and United Nations forces.

A new type of weapon developed during World War II and extensively used in Korea was the recoilless rifle. Ordnance designers had long dreamed of creating a weapon that would have no "kick," or recoil, and would therefore need no heavy recoil-absorbing mechanism. The dream was realized by designing a weapon that permits some of the propellent gases to escape through exhaust ports in the breech, thus giving the weapon a forward thrust equal to the normal recoil. Germany developed 75-mm. and 105-mm. air-borne recoilless weapons, and the U.S. army adopted powerful light-weight recoilless rifles of three calibres, 57 mm., 75 mm. and 105 mm. The 57-mm. rifle, weighing less than 50 lb., can be handled by one man as a shoulder weapon and may be classified under small arms. The 105-mm. was developed after the war to be mounted on a Jeep or fired from the ground. Recoilless weapons are characterized by their simplicity, lightness, vented breechblocks, perforated cartridge cases and pre-engraved shells (*i.e.*, with rotating bands cut to fit rifling). One of the greatest drawbacks to their tactical use is the rearward blast that betrays their location and makes them unsuitable for use in bunkers or pillboxes.

The most dramatic new artillery piece revealed by the U.S. army in the post-World War II years was the 280-mm. gun capable of firing both conventional and atomic shells. The first firing of an atomic shell occurred on May 25, 1953, at the Atomic Energy commission's proving ground near Las Vegas, Nev. The atomic gun has a range of about 20 mi. and is fired by a nine-man crew. It is carried suspended between two cabs, front and rear, that can transport their load on highways at a speed of 35 m.p.h. The complete unit ready for travelling weighs 85 tons and has an over-all length of 84 ft., 2 in. The entire carriage is balanced on a turntable to permit traverse of 360°. The projectile and powder charge are loaded into the breech by means of a hydraulic power rammer, though loading may also be done by hand.

Anti-aircraft artillery achieved a position of great importance during the first half of the 20th century as the aeroplane came into its own as an engine of war. Although calibre .50 machine guns on multiple mounts were effective in downing planes or forcing them to keep at a safe distance, the trend of development was toward more powerful long-range weapons such as the 20-mm. automatic cannon, the 25-mm. Japanese anti-aircraft and anti-tank gun and the 40-mm. Bofors gun, all of which have been widely used, along with the 37-mm. anti-aircraft gun. The 40-mm. gun was designed in Sweden and adopted by many nations. The model used by the U.S. army for anti-aircraft defense is air-cooled, fires at the rate of 120 rounds per minute and is accurate up to about three miles. The U.S. navy employs a water-cooled version of the 40-mm.

Three larger guns, the 3-in., 90-mm. and the 120-mm. "Stratosphere," were adopted by United States forces for defense against high-flying bombers. Germany employed 105-mm. guns for this purpose; the Japanese used 100-mm. and 120-mm. types. The most baffling problem in the use of such weapons is fire control, for they must be used against planes flying at great speeds and at heights of 30,000 ft. or more. Height finders and complex instruments known as directors or computers make the intricate calculations needed to aim the gun properly. As it is virtually impossible to score a direct hit on a high-flying plane, artillery shells are set to explode when they reach the estimated altitude of the aeroplane.

The most significant advance in anti-aircraft ammunition during World War II was the development of the V.T. or proximity fuze that causes a shell to explode when it comes within a predetermined distance of its target. Proximity fuzes contain a miniature radio sending and receiving apparatus that explodes the shell when the radio signal is reflected from the target (or other solid object). Proximity fuzes played an important role in defending ships against air attacks, countering the German "buzz bomb" attacks on England in 1944 (*see* below), and later in ground warfare on the continent.

In 1953 the U.S. army released information on a new automatic anti-aircraft gun called the "Skysweeper." A 75-mm. weapon, it has a built-in radar for tracking hostile planes and a computer that automatically plots the range, speed and course of the target plane. It fires $11\frac{1}{2}$-lb. high-explosive shell equipped with proximity fuzes at a rate of 45 per minute. It can detect approaching planes 15 mi. away and attack targets as distant as 4 mi. The entire unit weighs ten tons and can be towed by tractor or transported by plane.

Artillery Ammunition.—The best-known types of artillery ammunition are described as high explosive (H.E.), armour-piercing (A.P.), high-explosive anti-tank (H.E.A.T.), canister, smoke, illuminating or chemical. Some artillery shells are made to be stuffed with propaganda leaflets. In World War I shrapnel ammunition consisting of a shell filled with steel or lead balls and an expelling charge was widely used but became obsolete as high-explosive shell fragments were found to be more effective. An improved canister shell that bursts its casing in flight and scatters small but lethal steel missiles by centrifugal force was used in Korea by United Nations troops to combat the "human wave" tactics of the Chinese Communists. Unlike the older shrapnel, canister contains no chemical expelling agent.

A round of high-explosive ammunition is composed of a steel shell filled with an explosive, a fuze to detonate the explosive at the proper moment and a brass or steel cartridge case containing the propellent powder. There are also many other small but essential elements such as detonators, primers, boosters, adapters and safety devices. The fuzes on artillery shells are delicate and complicated mechanisms designed to detonate the explosive charge

upon impact or after a short delay. Most fuzes are placed in the nose of the shell and are called point-detonating, but some, particularly those used in shells designed for penetrating armour or concrete, are in the base. The explosive train in the fuze of an artillery shell consists essentially of three elements: a small quantity of very sensitive explosive, known as the primer, actuated by a firing pin; a less sensitive detonator that amplifies the weak primer impulse; a still less sensitive booster that amplifies the primer-detonator flash sufficiently to cause full detonation of the comparatively insensitive high explosive. (An explosive train is also used in artillery cartridge cases to ignite the propellent powder.)

Another type of ammunition utilizing the "shaped charge" or "hollow charge" principle came into use during World War II for penetrating armour. The standard A.P. round depended for its effectiveness on high velocity and use of a core of very hard material, such as tungsten carbide. The shaped-charge projectile was based on the so-called Munroe effect noted by a U.S. chemist, Charles E. Munroe, in the 1880s. The explosive charge in this type of ammunition is designed with a cone-shaped cavity (base forward), lined with metal, that focuses the effect of the blast on a central point. A remarkable feature of this type of ammunition is that its penetrating power is not a function of its velocity. It is used with low-velocity weapons such as the bazooka, with bombs or even with hand grenades and demolition charges.

Hand grenades are among the simplest types of ammunition, consisting basically of a steel case filled with a high-explosive charge detonated by a short-delay fuze. The traditional "pineapple" type (so called for its shape and outer case markings) is of a convenient size for throwing by hand. Other types are of many different shapes and sizes including the widely used "potato masher" grenade. Hand grenades are cheap, expendable and easy to use. The Soviet army is known to place great emphasis on them. In Korea the Chinese Communists made liberal use of hand grenades as offensive, defensive and anti-tank weapons.

Land mines are a special type of ammunition designed to be buried a few inches below the surface of the ground and to explode when the enemy unwittingly applies pressure to the ground above them. Instead of being buried they may be hidden and equipped with trip wires or other ingenious actuating devices that give them the name "booby trap." Mines fall into two classes—small antipersonnel mines and more powerful anti-tank mines. Both types may be used in areas being evacuated to hinder the enemy from occupying the ground, or they may be hastily planted around a newly won position as protection against counterattacks. Mines are sometimes equipped with antidisturbance devices that cause them to explode if efforts are made to remove them. Controlled mines are detonated by concealed observers while automatic mines are set to explode after a predetermined interval. To foil electronic mine detectors that reveal the presence of buried metallic mines, all major powers use nonmetallic mines made of wood, plastic or pottery.

Underwater mines have been widely used for many years for the defense of harbours. They are employed against surface vessels or submarines and some are placed in the shallow water along beaches to destroy small landing craft. The controlled mines used for harbour defense consist essentially of a buoyant case filled with an explosive, a firing device connected to a shore station, and a cable reaching to an anchor resting on the bottom of the harbour. A new type of contact mine, the magnetic mine, was developed in Germany and first used against the British in the fall of 1939. These mines contained a firing mechanism that was activated by the magnetic field surrounding a steel ship and did not depend upon bumping by the ship. The effectiveness of the magnetic mine was eventually nullified by the development of means to reduce the magnetic fields of naval vessels, a process known as degaussing.

Two main types of torpedoes (nicknamed "tin fish") are used by naval forces to attack enemy surface vessels or submarines. The first is the straight-running torpedo that maintains the course on which it is launched until it reaches its target or completes its run. The other is the target-seeking torpedo equipped with an acoustic system that adjusts its course to assure hitting a hostile submarine or surface vessel, even though the target vessel takes evasive action. Both radio-controlled torpedoes and torpedoes guided by the magnetism of a ship's hull have been devised. Launched by surface vessels, submarines, aeroplanes, helicopters or lighter-than-air aircraft, torpedoes are large and complicated mechanisms that carry several hundred pounds of explosive, have a long range and travel at high speeds.

Bombs.—Conventional bombs (excluding atomic or hydrogen bombs) are generally classified under three headings—demolition, fragmentation and chemical—although other terms are also in use such as general purpose (G.P.), pyrotechnic, incendiary or semi-armour-piercing (S.A.P.). Demolition bombs are designed to destroy the target by the blast effect of their high-explosive charge. They are the largest bombs, for they must carry as much explosive as possible, and have light cases. U.S. forces in World War II used demolition bombs ranging in size up to 4,000 lb., while the British used a 12,000-lb. "Tall Boy" bomb and developed a 22,000-lb. "Grand Slam" bomb. Depth bombs are a special type of high-explosive bomb used for attacking submarines or other targets under water, the damage being caused by the hydrostatic pressure created by the blast of the bomb. The depth bomb is larger than the depth charge, popularly called "ash can," hurled from surface vessels. The British developed a multiple mortar device nicknamed "Hedgehog" for launching depth bombs from destroyers, and the United States adopted a rocket launcher for this purpose with the name of "Mousetrap."

Fragmentation bombs are made with relatively thick cases that break into pieces when their small explosive charge is detonated and thus fill the air with flying steel fragments. They are most effective against such targets as enemy troops or parked planes when detonated a short distance above the ground. To achieve this effect and to permit low-flying launching planes to escape damage, they are sometimes equipped with parachutes that check their rate of fall. The so-called "butterfly" bomb is equipped with metal wings that unfold after the bomb is released, retard its fall and arm its fuze mechanically. In 1945 bombs with proximity fuzes (*see* above) were used by the Allies in the Pacific and in Europe to provide highly destructive air bursts.

Chemical bombs may be filled with chemical agents such as a smoke-producing substance, an incendiary material or an irritating or poisonous gas. They contain a bursting charge that disperses the chemical agent on impact. The increased use of incendiary bombs was one of the outstanding new developments in aerial warfare during World War II. Filled with thermit (aluminum and iron oxide) or magnesium, these bombs were rained down upon London during the blitz of 1940 and caused untold damage. In the war against Japan the United States used a new type of incendiary bomb filled with a gasoline jelly known as napalm. In its gelatinous state the gasoline burns for a long time and readily adheres to the walls of buildings. The napalm bomb is considered by many to be the single most devastating weapon used against the Japanese.

On a lonely desert area in New Mexico, in the semidarkness of early morning, July 16, 1945, the first atomic bomb exploded with a blinding flash and deafening roar. (*See* ATOMIC ENERGY.) The energy released was estimated to equal that of 20,000 tons of T.N.T. The new bomb was the product of nearly five years of intensive work by research scientists and engineers enlisted in one of the biggest military gambles in modern history. Starting in 1940 with little more than a scientific theory, British and U.S. scientists, significantly aided by refugee scientists from various European countries, telescoped a generation of research into a few short years and provided the Allied nations with a new weapon of awe-inspiring power. The official government press release described it as "a revolutionary weapon destined to change war as we know it, or which may even be the instrumentality to end all wars."

Only two atomic bombs were dropped in combat during World War II. The first descended on the Japanese city of Hiroshima on Aug. 6, 1945, and the second on the city of Nagasaki on Aug. 9. The effect in both instances was devastating and was credited with

speeding the Japanese decision to surrender before Allied ground troops had set foot on the Japanese home islands.

No sooner had the bombs been dropped than discussion was begun of means to outlaw their use in the future. The matter was taken up by the United Nations, but differences in viewpoint between the Soviet Union on the one hand and the United States and Great Britain on the other forestalled any progress. In 1946 the United States conducted extensive tests at the Bikini atoll in the Pacific to determine the effect of the bomb on naval vessels. In 1950 the U.S. announced that evidence was at hand to show that an atomic explosion had occurred in the Soviet Union. None of the belligerents used atomic bombs during the Korean war (1950–53).

Immediately after the atomic bomb became a reality scientists began speculating on the possibility of producing a vastly more powerful hydrogen bomb with explosive force equal to millions of tons of T.N.T. In Aug. 1953 the Soviet government announced that it had developed and tested a hydrogen bomb, and a few days later the United States government stated that it had learned through its long-range detection system that a hydrogen bomb had in fact been tested in the U.S.S.R. on Aug. 12. At the same time the United States government revealed that it had tested hydrogen bombs in 1951 and 1952.

Explosives and Propellants.—During World War II, as during preceding years, the most widely used explosive for ammunition was T.N.T., which could be employed by itself or in combination with other explosives. Its production was greatly increased by discovery of the reverse nitration process that doubled the capacity of existing T.N.T. plants, and its blast effect was enhanced by mixing T.N.T. with aluminum powder and other materials. The British used minol, a mixture of aluminum and amatol, and tritonal, a mixture of aluminum and T.N.T., in 4,000-lb. bombs and found they produced an area of devastation nearly twice that of bombs filled with T.N.T. alone. For certain applications T.N.T. was superseded by other explosive compounds such as cyclonite or R.D.X. (British abbreviation for research department explosive), haleite, ednatol and pentolite. Known long before 1940 but not employed as an explosive filling for shells because it was too sensitive, R.D.X. assumed a position of major importance as a military explosive only after a method for combining it with desensitizing agents was devised and a new mass-production process worked out. During World War II R.D.X. compositions were produced—composition A for shell loading, composition B for loading of bombs and composition C for demolition charges. Because its under-water blast effect is nearly double that of T.N.T., R.D.X. composition B mixed with powdered aluminum was widely used by British and U.S. naval forces under the name of torpex. Haleite (named for G. C. Hale of Picatinny arsenal), also known as E.D.N.A. (ethylene dinitramine), was used increasingly during the 1940s as improved processes for its manufacture were developed. For shaped charges (*see* above) a combination of T.N.T. and E.D.N.A. known as ednatol was adopted, and some use was also made of pentolite, a mixture of T.N.T. and PETN (pentaerythritol tetranitrate). As pentolite has more brisance (shattering power) than T.N.T., is readily detonated and can be easily loaded, many nations use it as a standard charge for bombs, land mines, rockets and high-explosive antitank shells.

As distinguished from high explosives, a propellant is a substance with a lower rate of combustion used to propel projectiles from weapons. The ideal propellant is one that gives high velocity, causes little barrel erosion, produces neither flash nor smoke, is easy to manufacture and is nonhygroscopic; *i.e.*, does not readily absorb moisture from the air. The United States uses single-base propellent powders, composed primarily of nitrocellulose, while most other nations use double-base powders containing nitroglycerine as well as nitrocellulose. The standard British propellant is cordite, a double-base powder. British forces also made some use of nitroguanidine in World War II, and the United States forces took an interest in it also in spite of the noxious ammonial fumes that had earlier caused it to be discarded. An improved manufacturing process for producing nitroguanidine was developed using less hydroelectric power than the process used in Canada during World War II.

Rockets.—As the early part of this article makes clear, war rockets are not modern inventions but weapons of ancient lineage which, after being neglected during the late 19th and early 20th century, reappeared in great numbers and in diverse forms during World War II. The Russians pioneered in firing anti-tank rockets from planes and in bombarding ground targets with massed rocket weapons. The British employed rockets for anti-aircraft and antisubmarine defense as early as 1940. Germany developed a multiple-tube rocket launcher to bombard enemy troops and in 1944 launched one of its most spectacular secret weapons, the long-range V-2 rocket (*see* below), against England. Later than other nations, the United States developed a wide range of ground and air rocket weapons.

Perhaps the most publicized weapon carried by Allied ground troops during World War II was the 2.36-in. bazooka, a rocket launcher firing a shaped-charge round with which an infantryman could knock out a tank if he hit a vital spot at close range. It consisted essentially of a six-foot tube, open at both ends, and a rocket projectile, and took its name from its resemblance to the musical instrument played by the comedian Bob Burns. To escape the backblast the operator did not hold the bazooka as he would a rifle but rested the middle of the tube on his shoulder. In the Korean war the 3.5-in. so-called superbazooka appeared for use against heavily armoured tanks.

The German counterparts of bazooka-type weapons were the light 88-mm. rocket launcher known as *Panzerschreck* (Tank Terror) or *Ofenrohr* (Stovepipe) and a heavy 88-mm. mounted on a two-wheel carriage. Among the many other rocket weapons employed by the Germans were the six-tube 105-mm. launcher mounted on a two-wheel carriage, a ten-tube 150-mm. launcher mounted on a half-track armoured vehicle, a five-tube 210-mm. launcher and a *Propagandawerfer* for firing leaflets. The German *Panzerfaust* weapons were recoilless grenade launchers but they did not fire rockets. For ground fighting where volume of fire was more important than accuracy, the Russians used rockets more than any other nation. Their two standard rocket launchers are the 16-tube 132-mm. and the 12-tube 300-mm. weapons mounted on trucks. Both England and the United States experimentally mounted banks of launching tubes on tanks.

As early as 1942 the Soviet air force used rockets to attack ground targets, particularly tanks, and in 1943 the Germans attacked Allied bomber formations with plane-to-plane rockets. Meanwhile the U.S. army adopted a 4.5-in. aircraft rocket launcher firing a rocket stabilized by fins that unfolded after the projectile left the tube. The U.S. navy developed a 5-in. high-velocity aircraft rocket (H.V.A.R.) nicknamed "Holy Moses" that saw combat use in 1944. The largest U.S. aircraft rocket to see service in World War II was the 11.75-in. "Tiny Tim" that carried an explosive charge of 150 lb. of T.N.T.

Beach barrage rockets fired from landing craft were significant innovations first used by the British in the invasion of Sicily. Continuously fed and automatically fired, each launcher could fire up to 30 rockets per minute, and some rocket ships mounted ten launchers. These small craft had, for brief periods, the striking power of destroyers and were able to saturate beach areas with close-in fire just before assault troops went ashore.

For antisubmarine attacks by aircraft two types of rockets were employed—forward-firing and backward-firing. The former had a long, shallow under-water trajectory suitable for attacking submarines. The latter was a scientific oddity that enabled a fast-flying plane to drop its bomb directly above a submarine instead of taking a long lead to allow for the forward motion imparted to the bomb by the plane. When the retrobomb was shot backward at the same speed as the plane was moving forward it dropped straight down on its target.

With these examples to illustrate the wide range of rocket applications we may consider briefly some of the basic features of modern rocket ordnance. All rockets fall into two classes—the liquid-fuel type such as the German V-2 and the solid-fuel rockets typified by aircraft and artillery rockets. The liquid-fuel type

carries a fuel, such as alcohol, and oxygen in tanks from which fuel lines lead to the combustion chamber. Solid-fuel rockets are powered by the burning of large sticks or grains of smokeless powder.

Rockets also fall naturally into two categories in terms of their means of stabilization in flight. As conventional artillery shell maintain stability in flight by rotation, one class of rockets operating on the same principle is known as spin-stabilized. The spin is imparted by the gases escaping through a ring of nozzles set at an angle to the rocket's longitudinal axis. The other type does not rotate but maintains its stability in flight by means of fins (comparable to the feathers used on an arrow) and is called fin-stabilized. The absence of spin is sometimes an important consideration because shaped-charge ammunition functions best when it does not rotate, but spin-stabilized rockets are easier to handle in the field and are usually more accurate than the fin-stabilized type.

Like other ammunition, rockets require propelling charges, and the development and manufacture of the various types of propellent powders must go hand in hand with the design and production of rockets and launchers. The two broad categories into which powders fall in terms of production methods are solvent and solventless. Both are double-base powders consisting of nitrocellulose and nitroglycerine. In the solvent type, a mixture of volatile solvents (alcohol and acetone) is used to assist in colloiding the nitrocellulose-nitroglycerine mass. After the powder is granulated, the solvents are removed by evaporation. For production of rocket powder in large grains or sticks the solvent method has two drawbacks—the long time required for drying, and the distortion of the grains during the drying period. In the solventless method the powder is colloided by means of heat, pressure and mechanical working and may be extruded by heavy presses into sticks that hold their size and shape. To get the desired burning qualities, sticks of rocket powder are often perforated and formed into unusual shapes—cylindrical, hexagonal, cruciform or star.

When used in weapons of the bazooka type, rockets lack the accuracy of conventional artillery, have much shorter range and far less velocity and do not function properly at extremely high or low temperatures. Their chief advantage is the absence of recoil that permits use of light launchers which are quite mobile and easy to manufacture. The 4.5-in. rocket and launcher, for example, weighs only 55 lb. as compared to 4,000 lb. for a 105-mm. (4-in.) howitzer. For aircraft armament, rockets provide a most useful intermediate weapon with fire power between the small-calibre machine gun and the bomb.

Guided Missiles.—The term "guided missile" covers such a wide range of weapons that only a cursory examination of their basic characteristics is possible in this brief space. Simply stated, a guided missile is a flying bomb or other projectile equipped with a device for directing its flight. The guiding device may be carried within the missile and may be of the preset type that will land the projectile after it has travelled a certain distance over a prescribed course, or of the target-seeking type that will cause it to "home" on a target by heat, radar, light or other form of energy. The controlling agent may be external, permitting guidance by radio from a ground station, an aeroplane or a naval vessel. To achieve guidance, elaborate mechanisms are sometimes used consisting of gyroscopes, servomotors, electronic devices, compasses, altimeters and many others.

Guided missiles are generally classified according to their tactical use as ground-to-air, air-to-ground, air-to-air or ground-to-ground. (Many other terms are sometimes used, as ship-to-shore or sea-to-air.) They may be propelled by conventional aeroplane engines, jet engines, rockets or, as with glide bombs, by force of gravity. They may be launched from the ground, from ships at sea (including surfaced submarines) or from aeroplanes. Long-range guided missiles travelling miles above the earth at supersonic speeds and carrying atomic warheads from continent to continent were regarded by many after the Korean war as the "weapons of the future." Consideration of their potentialities gave rise to much speculation about an era of "push-button warfare" that would render obsolete the piloted aircraft and the ground armies of the past.

Exaggerated claims must, of course, be discounted, but during the decade of 1940–50 guided missiles definitely moved out of the realm of science fiction and became grim military realities.

A simple type of guided missile is the pilotless radio-controlled "drone" aeroplane used for gunnery training, test flights or photo reconnaissance. During World War II old bombers equipped with automatic pilots (gyroscopes and motors that keep a plane on course) were loaded with high explosives and sent crashing against German submarine pens. Glide bombs, nicknamed "glombs," were fitted with wings that caused them to glide earthward and were subject to control by the launching plane. One U.S. type, named "Roc" after the giant mythological bird that dropped boulders on Sinbad's ship, had a television "eye" while another, named "Bat," emitted radar signals that were reflected from its target much as the sounds emitted by bats are reflected to enable these blind creatures to "see." The azon bomb was another type that could be guided to the right or left (*i.e.*, in azimuth only; hence the name "azon") by the launching plane. The razon bomb that could be guided in both range and azimuth and other U.S. missiles propelled by rocket or jet engines came very late in the war.

By far the most outstanding new developments with guided missiles during World War II came out of Germany. In mid-June 1944, just one week after the start of the cross-channel invasion, Germany launched the first V-1 (abbreviation for *Vergeltungswaffe Eins* or Revenge Weapon One) against London. It was a small aeroplanelike missile with a wing spread of 17½ ft., powered by a jet engine (not a rocket) and carrying about one ton of high explosive. As this "buzz bomb" travelled less than 400 m.p.h. at an altitude of 2,000–3,000 ft., and had a range of only 150 mi., British defense forces, using radar, anti-aircraft directors and fighter planes, were able to shoot down the V-1s with increasing success. Early in Sept. 1944 the Germans launched their first V-2 against England. This was a true rocket bomb, larger than the V-1, that travelled so high and fast that interception was impossible. Carrying its own fuel (alcohol) and its own oxygen, it rose to an altitude of 70 mi. above the earth and travelled so fast (more than 3,000 m.p.h.) on its downward plunge through the stratosphere that it reached its target before the sound of its coming was heard. Assembled in an underground factory, the V-2s emerged to trace a flaming path through the European skies and then crash to earth with terrifying explosive effect. German scientists also drew up plans late in the war for a so-called "American rocket" with range sufficient to cross the Atlantic ocean.

After the war's end the United States, Great Britain and presumably the Soviet Union made intensive efforts to build upon the foundation laid by Germany and to develop improved missiles. As early as 1945 the United States established in New Mexico the White Sands proving ground, a desert area more than 100 mi. long and 40 mi. wide, for study and test of captured German missiles and new U.S.-made devices. One of the outstanding events was the test firing at White Sands on Feb. 24, 1949, of a step-rocket—a German V-2 carrying in its nose a smaller 700-lb. rocket known as the Wac Corporal. After riding the V-2 to a height of 20 mi. or more the Wac Corporal automatically broke loose and, powered by its own rocket engine, reached an altitude of 250 mi. Searchers did not pick up any of the pieces of the Wac Corporal from the New Mexico sands for a full year. Many other tests of high-altitude, long-range missiles have been made, including the firing of a V-2 from the deck of an aircraft carrier, the launching from submarines of flying bombs similar to the V-1 and the ascension of a Viking (closest U.S. approach to the V-2) from the deck of a vessel in mid-Pacific to a height of more than 100 mi. on May 10, 1950. In 1953 the U.S. army released information on a new ground-to-air missile named Nike (for the Greek goddess of victory), said to be highly effective against high-flying planes. Launched from the ground by a booster that drops off after the missile attains enough speed, the Nike is steered by ground crews who track the target plane by radar.

Tanks.—The word "tank," originally used as a cover name by the British in 1916, became a part of accepted military terminology to denote a track-laying vehicle usually mounting one powerful

gun and several small-calibre machine guns, and providing all-round armour protection for its crew (*see* TANKS). Tanks are often classified as light, medium or heavy, depending on their over-all weight, or as light-gun, medium-gun or heavy-gun, according to the calibres of their primary weapons. Tanks are distinguished from gun (or howitzer) motor carriages by their fully enclosed and heavily armoured crew compartments.

In 1939–40 the German army startled the world with its blitzkrieg tactics wherein tanks and aeroplanes spearheaded the rapid advance of the infantry. Of the four German tanks used in 1940 (*Panzer* I, II, III and IV) only the Panzer IV carried a 75-mm. gun. They proved to be no match for the heavy Soviet tanks encountered during the invasion of the U.S.S.R. (1941). The Tiger tank used by the Germans in North Africa proved superior to the American Grant and British Churchill tanks. When the U.S. General Sherman appeared it served well until the heavier German Panther came on the scene.

At the time of the attack on Pearl Harbor the United States had a 65-ton heavy tank (M6) in production, but its manufacture was cancelled in favour of medium tanks of the General Grant and General Sherman types. The latter, weighing about 35 tons and in later models mounting a 76-mm. high-velocity gun, was more manoeuvrable than the proposed heavy tank. The 45-ton General Pershing tank with a 90-mm. gun appeared late in the war. Both the Sherman and the Pershing, as well as the light tank, General Chaffee, and the General Patton (M46), a modified General Pershing, saw service with the U.S. army in Korea. The British used the Centurion 50-ton heavy tank mounting a 20-pounder gun. One of the newer U.S. tanks was the Patton 48, a 45 to 50-ton vehicle with a 90-mm. gun, publicly announced in 1952. Another was a heavy tank carrying a 120-mm. high-velocity gun. The third member of the U.S. army's new tank family was a light 26-ton tank mounting a 76-mm. high-velocity gun and nicknamed the Walker Bulldog. The standard tanks of the Soviet army at the time of the Korean war were the T-34, a 35-ton medium tank carrying an 85-mm. high-velocity gun, and 50-ton heavy tanks (JS-1, JS-2 and JS-3) mounting 122-mm. guns. (*See* also AMMUNITION; ARTILLERY; GUNNERY, NAVAL; SMALL ARMS, DEVELOPMENT OF; also articles on individual weapons such as GUN, MACHINE; ROCKETS; etc.)

ORDOS: *see* SHENSI.

ORDOVICIAN SYSTEM, in geology a term introduced by Charles Lapworth in 1879 to include those rocks—well developed in the Welsh region formerly inhabited by the Ordovices—which had been classed by Sir Roderick Murchison as Lower Silurian and by Adam Sedgwick as Upper Cambrian (*see* SILURIAN). The Ordovician system is of rocks formed in the Ordovician period of time, a span of about 60,000,000 years that ended about 400,000,000 years ago, the duration and age being based on interpretations of the depositional record and on the present state of disintegration of radioactive minerals in associated rocks. The Ordovician period in current classification of geologic time followed the Cambrian period and preceded the restricted Silurian or Gotlandian period.

In the early part of the 19th century all the rocks which lie beneath the Carboniferous limestone were grouped together under the general name of Transition series, and it was not till 1831 that Sedgwick and Murchison made the first serious attempt to reduce them to order. Sedgwick started to work in the Snowdon district, and Murchison began upon the Welsh borders. By 1835 they had advanced so that Murchison gave the name Silurian system to the sequence of rocks with which he was dealing, while Sedgwick called his the Cambrian series. At the time it was supposed that the Cambrian lay entirely below the Silurian. Subsequently it was shown that the upper part of Sedgwick's Cambrian is the same as the lower part of Murchison's Silurian. A prolonged controversy followed which left its effects in some confusion of nomenclature even to the second half of the 20th century. Believing that the Cambrian and Silurian of Sedgwick and Murchison included three natural divisions, Lapworth in 1879 proposed that these be called Cambrian, Ordovician and Silurian. Murchison's terminology was still used to some extent at mid-20th century especially in Germany, the three divisions being called the Cambrian, the Lower Silurian and the Upper Silurian.

The three systems are universally recognized but there are some differences of usage with regard to their precise limits. Most British geologists adhere to a classification, based largely on original definition and structural considerations, in which the base is drawn above the Tremadoc, which includes the zone of *Dictyonema flabelliforme,* whereas in extra-British areas there is general adherence to the Scandinavian practice of placing the base below that zone. There is also some divergence of opinion as to the horizon at which the upper limit should be placed, particularly inasmuch as correlations among the several continents are not conclusive.

The strata composing the system can be classified in several contemporary lithologic facies deposited under differing physical conditions, and inasmuch as these evidence differing environments, each of the lithologies has an associated distinctive fossil assemblage. The lithologies vary continuously, geographically and temporally. Their textures and depositional structures can be related to the velocities of the currents that transported and sorted them and to the depths in which they were laid; their compositions reflect the materials that were carried into their places of deposition and the minerals that were precipitated locally by inorganic or organic processes. (1) Rocks of nonmarine origin include consolidated gravels (conglomerates), sands and clays having particles of sizes streams were incompetent to carry farther, as well as the original fluviatile structures. (2) Marine rocks ordinarily contain some significant organisms that substantiate recognition of origin from interpretation of their textures and structures. They are broadly separable into (*a*) those laid in shallow water, of depth of scores of feet or less, and (*b*) those laid in deeper water where currents and agitation were insufficient to prevent settling of fine particles. Each may be dominantly of inorganic detritus transported from lands, of minerals formed locally by precipitation, or from the accumulation of organisms and organic detritus. Those of shallow-water origin include shelly limestones (coquinas) and calcite sandstones (calcarenites), grading into quartz sandstones, graywackes (quartz-sandy argillites) and shaly and silty argillites deposited in seas receiving detritus eroded from lands; and from areas having limited circulation, dense limestones (calcilutites) and dolomites, and evaporites such as gypsum and salt deposits. Rocks of deeper-water origin pass through dense and nodular, somewhat cherty and argillaceous limestones into dark laminated argillites (black shales) and dense argillaceous limestone interbeds, prevalent in deeply sinking regions in which deposition failed to keep pace with subsidence. (3) There are additional and significant lavas and volcanic fragmental rocks.

Thicknesses are a measure of the subsidence of the earth's surface, fluctuations of sea level and the rate of deposition. The Ordovician rocks of the several facies are distributed in systematic but changing patterns that reflect the structural development within the areas of deposition, as well as the uplift and erosion

of adjoining lands.

The earth had several large, rather stable areas of continental proportions and varying relative elevation (cratons) separated by linear geosynclinal belts of greater mobility. The central parts of the geosynclinal belts had thick sequences of sediments, and volcanic rocks accumulated in rapidly sinking geosynclines (eugeosynclines) that gained detritus from near-by rising narrow islands; the typical Ordovician of Wales is of this facies. Adjoining are belts of nonvolcanic rocks of relatively great thickness (miogeosynclines), commonly decreasing rather rapidly at the margins of the cratons. The thicker rocks of the cratons are principally of shallow-water origin, increasing and diminishing in response to warping movements within their area; deeply sinking local regions occasionally gained deposits of geosynclinal proportions (autogeosynclines). This pattern is disturbed or destroyed as orogenies deform and raise the rocks of the linear geosynclinal belts, streams distributing the detritus into subsiding areas in the borders of the cratons (exogeosynclines).

Life.—The changing distribution and elevations of lands and the depths of the seas not only influenced the lithologies, but controlled physical and organic environments and restricted migration. Thus, Ordovician faunas exhibit changes with time, but also the effects of ecological factors and the isolation of geographic provinces.

The life of the system has several distinctive features; the changes from the older Cambrian and into the younger Silurian are not abrupt but are apparent to those familiar with the refinements of biological classification. Similar contrasts developed within the system not only in successive strata but among varying environments represented in differing present rocks. Few classes of organisms are common to faunas both of quartz and calcite sandstones and calcareous shales deposited in relatively turbid shallow water, and of black shales and dense argillaceous limestones laid in deep water; and such as are represented in each have distinctive families and genera. Trilobites that dominate Cambrian sediments of many lithologies continue in abundance, but become subordinate in numbers to other groups that had been absent or uncommon. Brachiopods, gastropods and cephalopods and later bryozoans, ostracodes, cystids, tetracorals and pelecypods became locally common in the limy and sandy lithologies, the shelly facies. The genera in each class are numbered in scores and hundreds, having smaller or greater temporal (stratigraphic) and geographic ranges; those of abundance in limited stratigraphic range are most useful in classifying and correlating the containing rocks in time. Graptolites, free-floating colonial marine organisms having individuals living in small cups (thecae) along raylike threads or branches (stipes) which when compressed seem like miniature deeply cut saw blades, are present in Cambrian rocks, but abound in some laminated Ordovician black shales; their fragile structures were not destroyed in the quiet and rather sterile environment of the clay deposition. Being free-floating (planktonic), they are more cosmopolitan, having many of the same genera and similar or identical species over the whole earth. The appearance of these forms is in fairly consistent order whether in Britain, North America or Australia, permitting rather confident general intercontinental correlation. They are the preponderant fossils in the black-shale facies and will serve as an example of changing life forms, such as might be repeated for any of many other biologic groups, though not with such world-wide prevalence.

Dictyonema, fan-shaped with connecting bars between the rays, is particularly prevalent in the basal Ordovician of the Scandinavian classification in beds classified as uppermost Cambrian in Britain. *Dichograptus,* with eight rays radiating from a central sac, *Tetragraptus,* two rays spreading from each end of a short bar, *Phyllograptus,* leaf-shaped when compressed but originally having an X-shaped cross section as of two interlocking leaves, and *Didymograptus,* tuning-fork shaped with the cups toward the centre, have wide distribution in the earlier Ordovician. *Nemagraptus,* having many long branches radiating from an S-shaped central rod, appears for a limited time near the middle of the system, with *Climacograptus,* like a single narrow leaf with cups on both sides, *Diplograptus,* similar with the cups more at an angle

to the stem, *Dicellograptus,* two branches diverging very broadly to form a very obtuse inverted V with exterior cups, and *Dicranograptus,* similar but an inverted V with cups toward the inside, having much longer range, some continuing to or into the Silurian. Graptolites abound with changing forms in dark shales of the Silurian system but are rare in younger rocks.

DISTRIBUTION

The rocks of the system are widely distributed but best known where they have been studied most intensely, in northern Europe and North America. Southern Europe has comparatively limited exposure of rocks as old as the Ordovician. In North America the system has been extensively preserved and penetrated by wells in broad areas where the rocks are concealed deeply. Knowledge in other continents is restricted by such factors as sparse surface distribution and severe deformation of the rocks and by the limited study that they have received over broad regions of the earth.

Europe.—The system was originally described from Wales, where it is of thousands of feet of graywacke and shale having thick lava flows and volcanic fragmental rocks, and is rather widely distributed in northern Europe. The northern European shield or craton has relatively thin sections, principally of carbonates, exposed in southeastern Norway, Sweden, Bornholm (Denmark), Estonia and east to Lake Ladoga in the U.S.S.R., and in southern Poland. Geosynclines having greater thicknesses of argillites, graywackes and volcanic rocks are represented in the Caledonide rocks of the northwest Norwegian coast, Scotland and Wales, in a belt from Cornwall and Brittany to western Bohemia and probably along the east side of the Ural mountains. Northwest of the Caledonides are isolated small areas with limestone sections; beyond the geosynclinal belt south of the craton are scattered areas, principally of argillites on the Mediterranean coasts and in the southern Alps.

The section in Britain has been divided into several series having zones with graptolite assemblages named for a distinctive species; authors differ in their delimiting of series, but the geological survey in Great Britain prefers the following classification:

Ashgill:	15.	*Dicellograptus anceps*
	14.	*Dicellograptus complanatus*
Caradoc:	13.	*Pleurograptus linearis*
	12.	*Dicranograptus clingani*
	11.	*Climacograptus wilsoni*
	10.	*Climacograptus peltifer*
	9.	*Nemagraptus gracilis*
Llandeilo:	8.	*Glyptograptus teretiusculus*
Llanvirn:	7.	*Didymograptus murchisoni*
	6.	*Didymograptus bifidus*
Arenig:	5.	*Didymograptus hirundo*
	4.	*Didymograptus extensus*
	3.	*Dichograptus octobrachiatus*
Tremadoc:	2.	*Bryograptus cambriensis*
	1.	*Dictyonema socialis*

The Tremadoc is usually placed in the Cambrian in Britain, conforming to the original definition; authors commonly do not add -ian or -an suffixes to names of series. Many prefer placing zone 6 in the Arenigian and zones 7 to 9 in the Llandeilian.

The Ordovician rocks of Britain were laid in a rapidly sinking volcanic geosyncline that passed from southern Ireland and western Cornwall through central Wales and the Lake district of Northwest England into southern Scotland. Islands on the northwest furnished the principal detritus, for the Arenigian laps over Cambrian and Pre-Cambrian in Anglesey, northwest Wales; and more than 2,000 ft. of Llandeilian and Caradocian in the Girvan district, southwest Scotland, overlaps Arenigian and has coarse sediment, whereas equivalent rocks near the English border to the east are the black shales (Glenkiln and Hartfell) with "condensed section" from the lower Caradocian through the Ashgillian totalling less than 200 ft. There are hundreds of feet of Arenigian lavas and

volcanic fragmental rocks in the Girvan district. The principal flows in the Lake district, the Borrowdale volcanics, thousands of feet of andesite and rhyolite, are Llanvirnian or Llandeilian. The typical Ordovician of North Wales has similar thickness in rocks ranging from Arenigian to Caradocian; the latter, the Snowdon volcanics, resistant to erosion, form the scenic highest elevations such as Mt. Snowdon. Volcanism continued locally to the end of the Ordovician, there being volcanic tuffs and flows of felsite in the Ashgillian of southwest Scotland. The rocks thin rapidly as they enter England, and in southern Shropshire, Caradocian lies locally on pre-Ordovician. These sediments are principally shallow-water types with shelly faunas, deposited on the margin of the gently sinking platform of the Midlands and southeastward.

England was along the southeastern border of a great volcanic belt that extended from Wales through the Caledonides of the Highlands of Scotland and the northwest coast of Norway, where areas such as Trondheim have thick sections of sediments and lavas. Northwest of this geosyncline, limestones that occupy a small area at Durness in the extreme north of Scotland and islands such as Smolen northwest of Norway are so dissimilar in lithology and faunas to those in the geosynclinal belt to the southeast that they are more readily compared with those in North America; Bear Island and Spitsbergen also have limestone sections. The Ordovician of the geosynclinal belt was severely deformed, and thrust faulted northwestward in Scotland, southeastward in Norway, in the Caledonian revolution after the Silurian; there are some areas having granites intruded within the Ordovician period.

Southeast of this geosyncline was a large area of relatively greater stability and thinner sections, the early Palaeozoic craton of Europe, occupying much of the region from the Caledonides and the Barents sea to the Urals and southward toward the Alps. The rocks have become exposed in scattered areas in southern Norway and Sweden, Bornholm, south of the Gulf of Finland, from Oland through Estonia to Lake Ladoga, and in south-central Poland. The Tremadocian lies on a slightly eroded surface of Cambrian, commonly with glauconitic sandstone at the base. Succeeding Ordovician rocks are rather constant in thickness and lithology over considerable areas and are principally limestones with abundant shell facies faunas, Estonia having particularly fine representation. The older series pass into graptolitic shales in Skane, south Sweden, and in the Oslo district, Norway, so that the temporal relations of facies and the correlations with Wales are generally known. The Silurian lies on varying Ashgillian horizons in Scandinavia and on Caradocian in Poland. Throughout the region there were no highlands, nor did uplifts in the adjoining geosynclinal belts contribute significant thicknesses of coarse detritus to the craton.

The Baltic belt of outcrop is rather isolated by the thick younger sediments of the Low Countries and the German and Polish plains from areas of exposure from western France through eastern Belgium, Bavaria and Thuringia to Bohemia. Inasmuch as wells have not penetrated the system in this great region, the character can only be induced. In Bohemia is the classic section of nearly a mile of Ordovician studied by Joachim Barrande. The older Tremadocian to Llanvirnian, mostly of graptolitic shales like those in the region along the margin of the Welsh geosyncline, has basic lavas and volcanics above the Tremadocian; coarsening graywackes and sandstones of the Caradocian and Ashgillian seem to have come from rising lands to the south. Similar sections are in southern Thuringia and Bavaria and westward through the Ardennes of Belgium into Normandy, where the Arenigian is the widely distributed, Armorican sandstone lapping over pre-Ordovician rocks. To the east, Ordovician calcareous and argillaceous rocks are present sparingly in the southern Urals; the eastern Urals have younger slates, cherts and volcanic sequences thrust westward, and similar rocks may have filled a geosyncline in the Ordovician. Thus the north European craton of the early Palaeozoic was margined on northwest, south and east by more rapidly subsiding geosynclines that were filled predominantly by argillites and graywackes derived from more distant lands or islands, and volcanic rocks of varying kinds, ages and thicknesses.

The Ordovician of southern Europe is exposed widely only in the Iberian peninsula, which in northwestern Spain and northern Portugal has overlapping Arenigian sandstone like the Armorican of France under graptolite-bearing shales and graywackes. Elsewhere north of the Mediterranean, outcrops have been so displaced by later structures that a comprehensive portrayal is not possible. Diminishing areas of land are considered to have extended in a belt from Brittany to western Bohemia; but Ordovician is present within the region, and the outline and distribution of the islands is not established. Similarly, the Iberian peninsula had land areas between a geosynclinal belt trending from the Pyrenees to the southern Alps and one through the western Mediterranean region. Shales and sandstones are prevalent in all these sequences.

North America.—The central part of North America in the Ordovician was a great shield or craton. Low-lying land of Pre-Cambrian crystalline rocks persisted in the northern half until late in the period; earlier sediments, principally carbonates, with some quartz sandstones thinned irregularly northward in the southern half. Belts of thicker carbonates (miogeosynclines) surrounded this relatively stable shield, the broadest belt being on the west. The peripheral parts of the present continent had deeply sinking geosynclines of dominantly argillaceous rocks, with interbedded lava flows and other volcanic rocks and thick graywackes and conglomerates that must have come from associated islands; these are the eugeosynclinal belts. These general relations were disturbed in the east in the middle of the period as uplifts in the peripheral areas were eroded, spreading detritus progressively over earlier carbonates, first in the miogeosynclinal belt, subsequently until they extended far into the craton, forming an exogeosyncline. Finally, the Taconian revolution severely folded and thrust-faulted the eastern geosynclines and thrust them toward the craton. The tradition has been that the early Palaeozoic North American shield had persisting geosynclines along its borders, Appalachian on the east, Ouachitan, Cordilleran and Franklinian on south, west and north, with great crystalline borderlands, Appalachia, Llanoria, Cascadia and Pearya, respectively, beyond. The margining geosynclines were of changing form, position and character, however, and the areas of the "borderlands" are known to have very thick sections of metamorphosed Palaeozoic sediments; sediments that have been attributed to the borderlands seem to have come initially from within the continent and subsequently also from lands raised in the geosynclinal belts.

The Ordovician, the most widely distributed system in North America, is usually divided into four series, having several groups:

Cincinnatian:	Gamache Richmond Maysville Eden
Mohawkian:	Trenton Black river
Chazyan:	Valcour Crown Point Day Point
Canadian or Beekmantownian:	Bridport Bascom Cutting Shelburne (possibly Upper Cambrian)

The Canadian is considered Lower, the Chazyan and Mohawkian Middle, and the Cincinnatian Upper Ordovician. The listed divisions of the Canadian are the formations in the type region of New York and Vermont, but reference is made more often to the sequence in the Ozark region in Missouri and Arkansas. Some would divide the Mohawkian into two series, Bolarian and Trentonian, the Black river group being within the former.

The classification is based principally on shell-facies faunas, but argillitic facies are well known and their relative positions established. The Canadian has Tremadocian to early Llanvirnian faunas from the zone of *Dictyonema flabelliforme* (Schaghticoke) to that of *Didymograptus bifidus* (upper Levis-Deepkill), though the latter may be somewhat older than the European *bifidus* zone. The Chazyan seems essentially Llanvirnian and Llandeilian, for

the basal Caradocian *Nemagraptus gracilis* zone (lower Normanskill) is about the base of the Mohawkian. Mohawkian and Cincinnatian faunas resemble Caradocian and Ashgillian though precise correlations have not been established, and the Upper Ashgillian may be included in rocks classified as lower Silurian.

The Canadian is of two principal lithologies, carbonates in the southern part of the craton, and in geosynclines along its margins; and in areas bordering the present continent, argillites and coarser sediments gained from adjoining islands, as well as volcanic rocks on the Atlantic and Pacific coast. The limestones and dolomites are in a narrow belt east of the craton from western Newfoundland to Alabama, a great area in the southern half of the craton where they thin northward, in a broad belt along the west from eastern Yukon and British Columbia through eastern Idaho, western Utah and eastern Nevada, southeastern California and western Sonora, and north as in northwestern Greenland. Sections along Lake Champlain in New York, Vermont and Quebec, and in the Ozark mountains of Missouri and Arkansas, are representative of this facies and have many genera of cephalopods, gastropods, brachiopods and trilobites. The graptolite sequence in the argillitic shales is known from many regions all around the continent, as scattered as central Newfoundland, eastern New York, Oklahoma, Nevada, southeastern Alaska and northern Greenland. Large boulders of carbonate facies of Cambrian and Canadian are found in the graptolite-bearing argillites south of the St. Lawrence river below Quebec city, and similar "exotic boulder" conglomerates are known in younger Ordovician in western Newfoundland. Some of the blocks being tens of feet long, their transportation has been attributed to submarine slumping in muds of rocks raised and dislodged, possibly by faulting, from the carbonate facies to the northwest. In central Nevada, Canadian and younger graptolitic slates and lavas form a sheet thrust more than 15 mi. on a section of folded sediments including contrasting Canadian carbonates; similar thrusts are known or suggested in many regions where the two facies are in proximity, making the determination of their original relations obscure.

The Middle Ordovician Chazyan and Mohawkian series are typically exposed on the east and west sides of the Adirondack mountains, northeastern New York. The former is limited in distribution or recognition on the continent. A remarkably pure wind-transported, water-laid quartz sand, the St. Peter sandstone, formed in a sinking embayment from central Michigan through Illinois toward the lower Mississippi river, probably in the Chazyan. The first phase of orogeny in the east was about the end of the epoch. Rising land in the Carolina region produced sands and clays that accumulated to a few thousand feet in a geosyncline in southwestern Virginia and eastern Tennessee; the argillites (Athens) having *Nemagraptus* grade into carbonates that thin rapidly westward. The succeeding lower Mohawkian Black river limestones are principally within the craton. Uplift east of New York in late Mohawkian (medial Trentonian) produced graywackes (Upper Normanskill-Schenectady) grading westward into black shales (Canajoharie and Utica) that thin rapidly along a northeast-trending axis passing through the present Adirondack mountains into shallow-laid limestones farther northwest. This narrow zone of gradation is recognized from Quebec to Virginia. Mohawkian carbonates of the interior are generally less than 1,000 ft., thinning irregularly northward so that Trentonian in central Canada lies directly on Pre-Cambrian, blanketing nearly all of the crystalline rocks so extensively exposed from the beginning of the Palaeozoic.

The Cincinnatian series has typical development in calcareous and argillaceous shales in Ohio, Indiana and Kentucky; the Edenian and Maysvillian are found only in the eastern states and southeastern Canada. The earlier Cincinnatian is detrital graywacke and shale (Lorraine) laid in a geosyncline, arcuate toward and extending into the continental interior, an exogeosyncline. The late Cincinnatian (Richmondian) seas retreated before the advancing deltas of fluviatile sands and gravels (Juniata) and red silts and clays (Queenston) from rising lands to the east. In the rest of the continental interior Richmondian carbonates and shales formed in the most widespread sea in North American history unless it be that of the latest Trentonian, over which the rocks commonly lie, the Edenian and Maysvillian being of restricted extent. The section of the Cincinnatian on Anticosti Island, Quebec, in the Gulf of St. Lawrence, is remarkable in its having a relatively continuous succession of latest Ordovician (Gamachian) and earliest Silurian fossiliferous shales and limestones. The Taconian revolution at the close of the period folded rocks from eastern Pennsylvania to Newfoundland and may have involved thrust faults of great displacement that brought the argillaceous facies upon the carbonate facies in the east.

Australia and New Zealand.—The Ordovician is well developed in a belt in Australia extending from eastern Queensland through New South Wales and Victoria into Tasmania, but is absent or sparsely known in the western half of the continent. Nearly three miles of slate and graywacke in southern Victoria form one of the finest sequences of graptolite-bearing shales in the world; the order of appearances of the genera is quite like that in Britain and America, and most of the forms are found in all continents. Lavas and pyroclastics are interbedded in the argillaceous rocks in a number of places, as in eastern New South Wales, southern Victoria and Tasmania, and the Upper Ordovician has phosphatic beds and cherts. Intrusions of granite are thought to have invaded the geosynclinal sediments in eastern Queensland at the close of the period. Shallow-water laid carbonates and sandstones are exposed at intervals in western Queensland, central and southern Australia, and reach thicknesses of a few thousand feet. In New Zealand, graptolitic argillites are present in the New Zealand alps of the South Island.

Other Continents.—Ordovician sediments are widely distributed in Asia and have been studied considerably, particularly in China and Manchuria, where the preponderant sediments are limestones. Argillites with graptolites are known in several areas, and are associated with volcanics in a belt in western Yunnan, along the Burma frontier. The Ordovician of South America is best known in a rather continuous belt along the west of the Brazilian shield from the Mendoza region, northwestern Argentina, through Bolivia and Peru to Cordillera Oriental of eastern Colombia and southern Venezuela; there are argillites, and limy beds having faunas more similar to those of the Ordovician of Britain and Sweden than those in North America. Ordovician rocks are of limited distribution in Africa, found principally in the north; in Morocco and northwestern Algiers are thick argillitic sequences. (M. Ky.)

ORDU (anc. *Cotyora*, where the "Ten Thousand" embarked for home), the chief town of a Turkish vilayet, on the north coast of Asia Minor, connected with Zara, and so with Sivas, by road, and with Istanbul and Trebizond by steamer. Filberts are exported. Pop. of vilayet (1950) 372,492; town 11,913.

ORDYN-NASHCHOKIN (or Ordin-), **AFANASY LAVRENTIEVICH** (d. 1680), Russian statesman under the tsar Alexis, was closely associated with the policy of westernizing Muscovite administration and economy while safeguarding the traditions of Muscovite life. The establishment of a postal service between Muscovy, Courland and Poland and the building of Russian merchant ships on the Western Dvina and the Volga were due to him. He negotiated the treaty of Andrusovo with Poland (1667) and hoped to secure for Russia an outlet to the Baltic by wresting Livonia from Sweden. But the tsar's growing opposition caused Ordyn-Nashchokin to retire to a monastery near his native Pskov, where he took vows (1672). His relatively humble origin, his knowledge of European affairs and his diplomatic integrity distinguished him from most of his colleagues; and his policy anticipated that of Peter the Great.

See E. Likhach, article in *Russky Biografichesky Slovar*, vol. xii (St. Petersburg, 1905); V. O. Klyuchevsky, *A History of Russia*, trans. by C. J. Hogarth, vol. iii (London, 1913).

ÖREBRO, a town of Sweden, capital of the district (*län*) of Örebro, lying on both banks of the Svartå a mile above its entrance into Lake Hjelmar, 135 mi. W. of Stockholm by rail. Pop. (1950), 63,521. Örebro was in existence in the 11th century. Its castle was erected by Birger Jarl in the 13th century, and 20 diets or important assemblies were held either in the castle or in the

town. Such were the Örebro *concilium* of 1537, the diet of 1540 in which the crown was declared hereditary, and that of 1810 when Bernadotte was elected crown prince. In great part rebuilt since a fire in 1854, Örebro has a modern appearance. An ancient castle, however, with four round towers, still remains, and is used as a museum. There may be mentioned also the church of St. Nicholas, of the 13th century; and the King's House (*Kungsstuga*), an old and picturesque timber building. The patriot Engelbrecht (d. 1436) was born there. The Swedish reformers of the 16th century, Olaus and Laurentius Petri, are commemorated by an obelisk. Örebro is the centre of the Swedish shoe industry; trade is carried on, by way of the Örebro canal and lakes Hjelmar and Mälar, with Stockholm.

ORE DEPOSITS. Minerals are naturally occurring substances of fairly constant chemical composition and physical properties. They make up ore deposits and rocks. In ore deposits, the minerals that give value to the deposit are the ore minerals, and the valueless minerals are the gangue minerals; the rock in which the ore is found is the country rock. The ore and gangue minerals are mined together—*i.e.*, taken out of the country rock in a mass—manually or mechanically. Thereafter the ore must generally be milled, the ore mineral being separated from the gangue mineral, usually mechanically. Next, the desired metal is extracted from the ore mineral by a chemical or metallurgical process; commonly this is a smelting operation. After this, the metal may be still further purified or alloyed with other metals, as in a copper refinery or a steel mill. Exploration, mining, milling and refining are thus successive steps in the utilization of an ore deposit to yield a metal.

By general agreement, ore deposits should contain metal-yielding minerals, should be of natural origin and should be economically workable. In a given instance, however, any of the three conditions included in this definition may be violated, provided the other two still hold. Thus, "ore deposits" is commonly applied to certain occurrences worked primarily for their nonmetallic elements, like the deposits of pyrite (FeS_2) mined in many industrialized countries as sources of sulphur gases and sulphuric acid. The accumulated waste, once useless, remaining after milling some ores may subsequently become a source of metals that can be extracted with profit; hence, it is at times, though rarely, called an ore deposit. Finally, the disseminated, lean deposits of copper minerals in granitelike rocks, occurring notably in parts of the western U.S., northwestern Mexico and Chile, were called ore deposits even before technologic progress made it possible to work them to economic advantage.

To be economically recovered the metals must be present as elements or compounds in concentrations far higher than normal in limited volumes in the earth's crust. The degree of concentration is shown by Table I, compiled from data by J. F. Kemp and F. H. Hatch; this contrasts the amount of a given metal necessary for profitable mining with the percentage of the metal in the rocks composing the earth's crust, as determined by F. W. Clarke (1924).

TABLE I.—*Metal Concentrations*

Element	Average percentage in earth's crust	Approximate percentage needed for profitable working
Aluminum	8.06	30
Iron	5.06	35-60
Manganese	.091	25-45
Chromium	.036	15-30
Nickel	.019	1.5-5
Vanadium	.016	3-8
Copper	.010	0.7-10.0
Zinc	.004	3-8
Lead	.002	2-4

For gold and silver the ratios of natural concentration to make a workable deposit in ordinary rocks are much more than those of the base metals. The figures in the third column require material qualification if by-products are obtainable, as is commonly the case.

As almost every rock contains at least a small quantity of almost every ion, the detection of desired metals is limited virtually by the sensitivity of the analytical method available, extending even to the small quantities of copper, lead and manganese in plant ashes. The widespread occurrence, but rare concentration, of the metalliferous minerals has affected the theories for the genesis of ore deposits and the methods of searching for them.

Classification and Genesis.—Before the 20th century, a favourite classification for ore deposits stressed their composition—iron deposits, gold deposits and so on. This method lacked any genetic significance, for iron-ore deposits can originate in several different ways. Furthermore, it ignored the fact that many ore deposits have two or more metals in abundance; the tin veins of Cornwall in Britain also yielded copper, the zinc deposits of Silesia carried noteworthy quantities of lead, and Cerro de Pasco in Peru had become by the middle of the 20th century an important source of zinc, though previously known for its copper production. In fact, the practical miner finds it necessary to apply such terms as "argentiferous lead deposits" to mixed ores like the silver-lead deposits in Murcia in southern Spain, or "dry gold ores" to the gold-quartz ores free from base metals.

A second basis for classification, as illustrated by the comprehensive system of Bernhard von Cotta (1808–79) and others, stressed the geometrical form of the ore body. Thus, Albrecht von Groddeck, a follower of Cotta, in 1879 distinguished bedded deposits, massive deposits and clastic deposits (including placers). Classification by form serves well in the search for an extension of a known ore body or for other similar bodies in localities where deposits have been found previously. Understandably, the application of this classification led almost insensibly to a genetic grouping through the schemes presented in 1881 by A. W. Stelzner, in 1903 by Kemp and in 1909 by Richard Beck.

The most scientific mode of classification is genetic. It may be attributed to the great controversy between the "Neptunist" A. G. Werner (1750–1817) on the one hand and the "Plutonists" James Hutton (1726–97) and John Playfair (1748–1819) on the other. This controversy turned on whether most mineral deposits were to be regarded as laid down in the sea, as suggested by Werner, or as injections or fissure fillings essentially from melts or hot solutions, as the "Plutonists" maintained. Despite widely held views to the contrary, both concepts held much truth. Later scientific followers continued this discussion on more quantitative grounds, but the front shifted somewhat; F. von Sandberger (1826–98), Groddeck and others stressed the derivation of the ore ions (*e.g.*, zinc in deposits of the zinc sulphide mineral sphalerite) from the country rock and their deposition in openings of that rock, a concept usually called lateral secretion. The transportation in such a process has been variously assigned to cool surface waters, later laterally moving (as by C. E. Siebenthal for the zinc and lead ores of the Tristate, Missouri-Oklahoma-Kansas district, U.S.) or to waters of the same origin which, though originally cool, had been heated by contact with hot rocks at depth and had subsequently risen, depositing their dissolved matter as they rose and cooled, as urged by C. R. Van Hise. Since it was at first believed that all waters, even the hot ones, were merely reheated surface waters and were, in fact, notably lacking near volcanoes, where molten rock comes to the surface and can be observed, it was generally contended that few or no solutions could have come up from deep inside the earth, carrying valuable metallic or other ions. But between 1910 and 1920 came confirmation of the large quantities of water and other adequate solvents of metals (such as ions of chlorine and fluorine) in the gases given off by certain carefully observed volcanoes, notably those of Hawaii (A. L. Day and E. S. Shepherd, 1913) and Katmai, Alaska (C. N. Fenner, 1920; E. G. Zies, 1924). Thereupon the viewpoint had to be abridged that excluded completely the role of solutions and ions of deep origin, probably related to deeply buried molten lavas; *i.e.*, "magmatic." The volcanic data combined with physicochemical inferences strongly supported the "hydrothermal" school of economic geologists represented by Waldemar Lindgren, J. H. L. Vogt, W. H. Emmons, J. E. Spurr, Paul Niggli and Hans Schneiderhoehn, who derived both ores and their transporting solutions in large part from magmatic sources.

By 1950, however, there was discernible a swing of the pendulum toward a modified lateral secretion idea, advanced in England by the writings of H. H. Read (1939), in the U.S. by those of G. E.

Goodspeed (1952), in Australia by those of C. J. Sullivan (1948) and in France by those of R. Perrin and M. Roubault (1939), all of whom suggested or hypothesized that some of the granitic rocks of the earth's crust may be remelted or recrystallized sediments. These or their followers inferred that during granitization, ore minerals may be generated or transferred. Even Niggli thus explained some of the "alpine" mineral deposits. This concept sought to derive the metalliferous minerals for the most part from deeper crustal or subcrustal sources, rather than from local masses of molten rock, and to attribute mainly to heat gradients and ionic diffusion the movements of the metal ions essentially to their present sites. If this process is effective, the ionic radii of the metallic elements concerned may well be a modifying factor.

Certain ore deposits were regarded by Vogt, A. P. Coleman and others as magmatic segregations. The minerals composing these were attributed to separation from the molten rock as a result of partial or complete immiscibility with the other rock constituents. Such ore minerals are generally sulphides or oxides of base metals (such as iron, chromium, copper and nickel) but they include native (elemental) metals of the platinum group and possibly also metallic iron. Many of the great nickel deposits (*e.g.*, Sudbury in Ontario, Petsamo in Finland), most of the known chromite deposits (Selukwe in Southern Rhodesia, the Stillwater deposits in Montana), probably many of the iron deposits made up of the mineral magnetite (Fe_3O_4) whether with or without titanium (as at Kiruna in Sweden, at Tahawus in New York and elsewhere) are generally regarded as of this origin. The original concentration of the platinum in the rocks of the Ural mountains of the U.S.S.R. is best explained in this manner. For some deposits of this general type the origin appears to be a separation in place of the ore from the gangue minerals, such as the feldspars (*q.v.*), quartz (*q.v.*), olivine (*q.v.*), the micas biotite (*q.v.*) and muscovite (*q.v.*) or the amphiboles (*q.v.*) or pyroxenes (*q.v.*)—the major constituents of the once molten (igneous) rocks that contain the ores. For others (*e.g.*, Kiruna) studies at mid-20th century seemed to show that a melt, unusually rich in ore minerals, was separated at depth and subsequently emplaced as a melt, injected into the containing rock after the latter had itself undergone injection and solidification.

Some ore deposits are closely related to intrusions of apparently molten rocks in the sense that they occur in or near such rocks, as a more or less continuous halo around the now solid mass. Such a melt has lost some of its more volatile constituents in the crystallization process (a theory developed by Niggli, Fenner and others), and the volatile matter moved into the adjacent, unmolten rock, usually a limestone or at least generally a rock carrying appreciable quantities of carbonates such as dolomite (*q.v.*) or calcite (*q.v.*). The volatiles reacted with the rock surrounding the igneous intrusion, giving a halo, made of "skarn" or tactite in which the ore minerals may be concentrated. Once interpreted as the effect of mere recrystallization of the materials present in the surrounding limestone or other sediment (W. L. Uglow, 1913) but later recognized as the result of a reaction between intruding and intruded rock, such deposits have been called "contact metamorphic deposits" (the pyrometasomatic deposits of Lindgren). The importance of the process in ore deposition was still being debated at mid-20th century (Harrison Schmitt, 1948).

None of the concepts outlined above is contrary to the nonmagmatic origin of certain clearly sedimentary ore deposits, such as the iron ores of eastern Britain, those of Belgium, Lorraine and eastern France (minette ores), those of the Clinton type in the eastern U.S., and of the Wabana district in Newfoundland. The widespread banded iron ores existing in the older (Pre-Cambrian) rocks of the Crimean region (Krivoi Rog) in the U.S.S.R., and other similar ores of India, the Lake Superior region in North America, the Labrador and Ungava regions in Canada and the Pre-Cambrian terrains of Venezuela and Brazil are likewise clearly sedimentary, as are the great bedded manganese deposits of Nikopol and Chiatouri in the Ukraine and Georgia, U.S.S.R. Sedimentary ores are formed by decay of surface rocks, which contribute the necessary ions to the lakes or the sea, where they may be precipitated by evaporation, chemically or biochemically (by action of bacteria, algae or the like). Evaporation has contributed important salt and potash beds in various regions but seems to have had little part in the formation of ore deposits. Streambed or marine deposition may also take place mechanically, yielding placer deposits if the minerals concerned are sufficiently resistant to the chemical attack of the atmosphere and to impact when carried as particles by streams. Placers of world importance are the titanium-bearing beach sands of Travancore, India; the gold-bearing stream gravels of the Sierra Nevada and Western Australia; the platinum gravels near Sverdlovsk on the eastern slope of the Ural mountains and those of Colombia; and possibly the gold-bearing conglomerate beds of the Witwatersrand, Union of South Africa.

Despite much discussion as to the derivation of the metallic ions in ore deposits (whether from country rock or magma) and their mode of transfer (whether in solution or by diffusion), the general grouping of the resulting deposits is fairly clearly defined and agreed upon, as a result of collective efforts through more than a century by many mineralogists, petrologists and economic geologists. The classes now generally recognized were perhaps best defined by Lindgren (1913), who separated all ore deposits into magmatic segregates, contact metamorphic deposits, pegmatites, veins and veinlike deposits of differing degrees of intensity in temperature and pressure (hypothermal, mesothermal, epithermal) and sedimentary deposits. For completeness these classes were modified, in part by subdivisions, and additional kinds of origin were recognized. Lindgren and those previously listed as sharing his views, as well as many later investigators, regarded the magma as containing the metallic ions of the ore minerals while deep down in the crust; the mass, while crystallizing there, loses its volatile constituents; these pass off, chiefly upward, depositing the ore minerals in pre-existing openings, or "fluxing" their way upward by dissolving the superincumbent rocks and finding room for ore deposition by a replacement or metasomatic process. Highly concentrated solutions of volatiles, localized in the igneous rocks from which they separated, give, according to this school, the pegmatite veins or dikes that are of much importance as sources of nonmetallic minerals (mica, gems, etc.) and at times of elements useful in the metal industry (*e.g.*, beryllium).

A fundamental basis for the classification given above is the temperature of formation of the ores. By observing the behaviour of the inclusions in the ore minerals as the temperature is raised (W. H. Newhouse, 1933); by recording the temperatures at which certain minerals in the ore deposits break down when heated (the "decrepitation temperature," F. G. Smith, 1947); by a comparison of textures suggesting the unmixing of solutions at known temperatures; and by means of basic data on inversion temperatures of the minerals present, attempts have been made to set exact limits governing the origin of these deposits. Such evidence, though useful, is admittedly still inconclusive and, like the theories for the genesis of individual deposits, is constantly undergoing revision.

A very striking feature of the primary mineralization of ores is the fact that the contents of a given ore deposit may change upward or laterally. In the tin deposition of southwestern Britain (Cornwall) an ore body which at depth yields chiefly tin-ore minerals, may pass upward into a predominantly cupriferous ore, and at the surface become essentially a zinc or lead deposit (W. R. Jones, 1925). The central, copper-rich part of the Butte, Mont.. mining district passes laterally into silver-bearing zinc ores and these give way to silver-bearing manganese veins and even into galena-bearing ore bodies (W. H. Weed, 1897; R. H. Sales, 1908). In fact, L. de Launay (1900), Spurr (1907) and W. H. Emmons (1924) developed in detail the sequence of mineralization from deep to shallow deposits which can be traced through the following ions: tin, tungsten, arsenic, copper, zinc, silver, lead, antimony, mercury; the position of iron and gold, among the common metallic ions, is varied and anomalous. A somewhat similar effect, extending also to certain gangue minerals, is noted with contact metamorphic deposits (V. M. Goldschmidt, 1911; Spurr, Fenner, G. H. Garrey, 1908, 1912). Such compositional changes are called zoning.

Secondary Changes in Primary Ores.—The processes described above yield the ore minerals as freshly deposited (pri-

mary), before being acted upon by atmosphere or cold surface waters, circulating downward. Examples of the more common primary ore minerals are given below:

Iron		Copper		Silver	
Fe_3O_4	magnetite	Cu	native copper	Ag	native silver
Fe_2O_3	haematite	$CuFeS_2$	chalcopyrite	Ag_2S	argentite
$Fe_2O_3.nH_2O$	limonite	Cu_5FeS_4	bornite	Ag_9SbS_6	polybasite
$FeCO_3$	siderite	Cu_2S	chalcocite	Ag_3AsS_3	proustite
FeS_2	pyrite	$Cu_8Sb_2S_7$	tetrahedrite	Ag_2Te	hessite
iron silicates		Cu_3AsS_4	enargite		
Aluminum		Zinc		Gold	
aluminum silicates		ZnS	sphalerite	Au, Ag	electrum
alkali alum silicates				Au	native gold
		Lead		$AuAgTe_4$	sylvanite
Tin		PbS	galena	Au_2Te	petzite
SnO_2	cassiterite	Nickel		Mercury	
Cu_2FeSnS_4	stannite	$FeNiS_2$	pentlandite	HgS	cinnabar

Most common primary ore minerals are sulphides or oxides; some are tellurides, native metals, carbonates, silicates or sulpho salts (double salts of the metal sulphides and sulphides of arsenic or antimony). Some of the minerals carry only one metal (*e.g.*, pyrite, FeS_2); others carry two or more metals (*e.g.*, stannite, Cu_2FeSnS_4).

After such primary ores are formed, the surface is slowly lowered by processes of weathering and erosion. At and near the surface, these processes act upon the ore minerals as upon other rock materials; in fact, even at some depth these minerals are attacked by waters, which, moving downward from contact with the air, transport oxygen, carbon dioxide and other materials in solution. Under these conditions the oxides and native metals are generally stable. The other minerals, however, tend to be converted to relatively soluble compounds. This applies especially to the sulphides, which, for the most part, become highly soluble sulphates. Copper sulphides become soluble copper sulphate which generally travels farther down with the descending ground water. Below the level of saturation, however, the oxygen supply to this water is cut off, reducing conditions prevail (especially in the presence of more sulphides of the primary ore, together with the sulphuric acid in the water), and eventually the copper tends to precipitate out as sulphides, such as chalcocite and covellite (CuS). This is characteristic of the zone of secondary sulphide enrichment. As this precipitation is greatest where the descending copper-bearing solutions first come into the zone of reduction, the effects of such reprecipitation of copper taper off downward. If, however, the downward moving, acid waters, while still above the zone of saturation and reduction, encounter a reagent (*e.g.*, the calcium carbonate of a bed of limestone) that neutralizes the acid, a reaction takes place which throws down the copper (generally by replacement) as a copper carbonate, the calcium ions travelling on in sulphate solution; in siliceous rock, the copper may similarly be precipitated as a silicate; or, in the presence of a strong oxidizing agent, the copper may precipitate as copper oxides or native copper. These minerals characterize copper deposits in the near-surface zone of oxidation.

If gold or its compounds occur in the primary ore, the relatively unstable telluride compounds are broken down into metallic gold, and the insoluble gold is concentrated in the oxide zone except in the presence of manganese dioxide and chloride compounds, which together yield the strong solvent, Cl^-.

Iron sulphides on oxidation yield sulphuric acid and the unstable ferrous sulphate. The latter is oxidized to ferric sulphate which then hydrolizes to ferric hydroxide, and eventually a precipitate of limonite or a related mineral is formed. In general, zinc sulphide behaves like copper but primary sulphides are more soluble. Lead sulphide, however, oxidizes rather easily to the poorly soluble sulphate (cerussite). Silver minerals behave like copper minerals but may be stabilized in the zone of oxidation if there are halogens present. Manganese resembles iron in reactions.

A special kind of change in primary ores is summarily described as residual concentration. In this, the effect of solution (leaching) by surface waters in the zone of oxidation is to dissolve and remove the gangue minerals, and in cases to stabilize the desired metallic ions still further. Thus relatively small quantities of iron carbonate in a limestone (composed of $CaCO_3$) may be converted to limonite; meantime the limestone is dissolved, if the surface water is rich in atmospheric carbon dioxide, approximately thus:

$$CaCO_3 + H_2O + CO_2 \rightarrow Ca(HCO_3)_2.$$

If the iron content of the limestone was originally only 5%, the removal of all the limestone by solution would yield natural iron ore bearing about 48% iron. Such a process is facilitated by moisture, the presence of vegetation (yielding the solvents humic acids and carbon dioxide), a warm climate (to accelerate the reaction and to permit plant growth), good drainage (at least, periodically, as in a climate with dry and wet seasons alternating) and a topography high enough to promote drainage but not so high that most of the rainwater will run off instead of penetrating to do its important chemical work at the surface and just below it. Examples of such concentration are the secondary manganese ores of the Gold Coast; the bauxitic aluminum ores of the Guianas; the residual iron ores of Moa and Mayari, Cuba; and the gold ores of the southern Appalachians. Inimical to such a process is everything that strips the soil rapidly, such as glaciation or rapid erosion. As applied to the marked enrichment in gold, this process is called eluviation; when applied to iron, manganese and aluminum ores, it is lateritization and the resulting ore is called laterite.

A table, illustrative rather than complete, is included to show the changes in the composition of ore deposits after oxidation and secondary sulphide enrichment.

TABLE II.—*Depth Zone Below Surface*

Metal	Zone of oxidation	Secondary enrichment zone	Primary ore
Iron . .	$Fe_2O_3.nH_2O$ (limonite) Fe_2O_3 (haematite)		$FeCO_3$ (siderite) FeS_2 (pyrite) Fe_3O_4 (magnetite) Fe_2O_3 (haematite) Iron silicates
Aluminum .	$Al_2O_3.H_2O$ (diaspore) $Al_2O_3.2H_2O$ (bauxite) $Al_2O_3.3H_2O$ (gibbsite)		Rock-forming minerals such as clay minerals, feldspars, etc.
Manganese .	MnO_2 (pyrolusite) Mn_2O_3 nH_2O (psilomelane) etc.		$MnCO_3$ (rhodochrosite) Manganese silicates
Copper . .	Cu (native copper) Copper oxides Copper carbonates Copper silicates	Copper sulphides, especially Cu_2S (chalcocite), CuS (covellite)	$CuFeS_2$ (chalcopyrite) Cu_5FeS_4 (bornite) Copper sulpho salts
Zinc . .	$ZnCO_3$ (smithsonite) $ZnSiO_3.Zn(OH)_2$ (hemimorphite)	ZnS? (wurtzite?)	ZnS (sphalerite)
Lead . .	Residual galena $PbCO_3$ (cerussite) $PbSO_4$ (anglesite)		PbS (galena)
Silver . .	AgCl (cerargyrite) and other halides Ag (native silver)	Ag_2S (argentite)	Ag (native silver) Ag_2S (argentite) Silver sulpho salts Silver tellurides
Gold . .	Residual native gold		Ag, Au (electrum) Au (native gold) Gold tellurides

This sequence of alteration may greatly complicate the richness of the ore at changing depth. Many of the disseminated copper ores (*e.g.*, Bisbee, Ariz., and Chuquicamata, Chile) are of moderate richness at the surface, where the once-exposed primary ores have had some of their copper and other, valueless, components removed; at depth, however, in the zone of secondary sulphide enrichment, they become richer, the tenor (grade) rising to perhaps twice the figure for the surface zone. At still greater depths the ore values decline to perhaps half those of the oxidized zone and the metal content may decline from a useable ore to a protore, unprofitable today but perhaps workable in the future after natural enrichment takes place or cheaper working methods are developed or copper prices rise. Abrupt differences in the vertical level of these three zones may result horizontally from movement along fault planes or differences in surface conditions affecting ingress of surface waters, drainage or the like.

Forms, Structures and Textures of Ore Deposits.—In the past, ore deposits were also classified on the basis of form, or other large-scale features, collectively spoken of as structure, but it

appeared later that this was not a feature fundamental to genesis and such classifications were abandoned. None the less, the form of a given ore body is of great practical importance in the search for ore extensions or for analogous bodies in near-by localities under similar geologic conditions. Thus, in the early half of the 20th century, stress came to be placed upon the geologic structures (faults and folds in the rocks or dikes [*q.v.*], sills [*q.v.*] and larger intrusions of igneous rocks) that might be the cause for localizing the ore or have exercised structural control on ore deposition. This school of investigators, among whom Canadians such as M. E. Wilson and E. L. Bruce, South Africans such as Ben Lightfoot and Americans such as B. S. Butler and G. M. Fowler merit mention as leaders, stressed the geologic structure rather than the mineralogy of the ore or the country rock—a natural outgrowth of the more intensive search for ore prevailing in a period of very abrupt rise in consumption rate.

The simplest types of ores from the structural viewpoint are the bedded or stratiform ores. In the strictest sense these consist of ore minerals deposited like any other sediment. If not too greatly deformed they may exhibit intertonguing, channelling, fading out, gradation of grain, ripple marks, fossils and other features of sedimentary rocks. They may be intensely folded, as shown by the Pre-Cambrian iron ores, or suffer thrust or normal faulting, like the minette iron ores of western Europe or those of the Clinton belt in the U.S. Among special types of sediments are the placer deposits already mentioned. The forms and other features of placers particularly resemble those that go with coarser clastic sediments, such as cross bedding and channel deposits. Concentration of the desired mineral may be in the inside of the meanders, the slipoff slope of bars or the lowest part of the bed, yielding accumulations that are locally especially rich (the "pay streak"). If deposition of ore minerals is by replacement of soluble minerals or by filling of pore space in a given stratum, the appearance of the ore may suggest a sedimentary deposit, even though ore deposition was much later than sedimentation. A special case is penecontemporaneous replacement, by which, apparently while falling to the sea bottom or shortly thereafter (during the solidification of a given sediment), such rocks as the limestones may have some or all of their constituents replaced by iron compounds.

Many ore deposits are apparently simple fissure fillings (fissure veins), transverse to pre-existing rock structures (*e.g.*, bedding) or parallel to them, as in bedded veins. If the former, they may indicate planes of shear or of tension, depending on their relation to the tectonic history of the region, which thus becomes of special interest. In closely studied districts (*e.g.*, the Erzgebirge, Saxony; the Mother Lode and Grass valley, California; and Braden, Chile), both the opening and the mineralization have proved to be repeated. This may well account, at least locally, for the wide veins of certain mining districts; other explanations for such veins include (1) a dense, essentially viscous and meltlike mineralizing solution (Spurr's "ore magma"); (2) an opening standing several feet wide, gradually filled with ore that crystallized from dilute solutions; (3) replacement (*e.g.*, solution of the country rock, with simultaneous deposition of the ore minerals) rather than open-cavity filling. Fissure fillings include such distinct types as ladder veins, small fissures between two or more bordering fractures; gash veins, several small fissure veins frequently overlapping; sheeted zones, many smaller subparallel veins making up a compound vein that is large but not simply one fracture; saddle reefs, veins in openings where beds separate at the crests and troughs of folds; zigzag veins, the direction or inclination changing as differing rock types are crossed; thinned or thickened veins, the changes taking place in a vein where it crosses from one rock type to another; breccia veins, with numerous fragments of the country rock in the plane of the vein and partially embedded in the vein material; an ore "pipe" or "chimney," a body of ore saturating and cementing a shattered rock mass and having one long dimension and two lesser dimensions. Larger fissures commonly break up into many smaller ones at their ends—upward, downward or laterally. Much attention has been given to the causes for the various forms of fissure veins.

Irregular forms include ore bodies apparently resulting from the filling of irregular caverns (though such cases are probably few); from the segregation of ore within an igneous mass in place; or from replacement, the simultaneous solution of country rock and deposition of ore, especially where ore solutions react with the country rock, as where a granitic rock is irregularly replaced by copper-iron sulphides (*e.g.*, the main ore body disseminated through the granitelike mass at Bingham, Utah) or where a limestone or dolomitic (magnesian) limestone is replaced by irregular masses of zinc and lead sulphides, with diameters ranging from microscopic to tens or even hundreds of feet. Several genetically different classes are thus included among the ore deposits of irregular form. There is not uncommonly a gradation from a fissure vein to an irregular body as a fissure vein enters a rock readily attacked by the ore solution.

The textures of ore bodies are their more minute characteristics. Thus, sedimentary ores are commonly oölitic, with particles like the *Bohnenerz* (bean ore) of many sedimentary iron ores; their texture consists of small spheres, frequently concentrically banded, up to half an inch but generally much less in diameter. A similar feature, though on a larger scale, is common in oxidized ores as in the beautiful concentric (botryoidal, mammillary) banding of head-sized masses of the bright green basic copper carbonate malachite. Such features, especially if characterized by syneresis (dehydration cracks), are regarded by many as evidence of colloidal deposition, hence called colloform textures.

A mineral in a replacement ore may have the crystal form of the preceding (host) mineral and is then known as a pseudomorph of the later. Fillings in open spaces are likely to show a sequence of mineral deposition, the first minerals formed being nearest the wall rock; the centre may remain unfilled. Studies of these and other textural relations yield an idea of the sequence of mineral formation or paragenesis. From 1920 onward, the reflecting (metallurgical) microscope (*q.v.*) proved a valuable tool not only to identify opaque ore minerals but also to study and interpret their microscopic textures in terms of their paragenesis and their origin.

In addition to picturing the larger or smaller features of an ore, the attitude and position of an ore body must generally be described, to aid the mining engineer or miner in extracting it. In the case of irregularly shaped ore bodies, this is generally a matter of citing detailed measurements in many places. Alternatively, a series of sections across the ore body may be presented or a three-dimensional model may be prepared by mapping successively deeper levels on glass planes supported in a frame, or by making a plastic or wooden model.

For tabular ore bodies, such as bedded ores or simple fissure veins of some size, the nomenclature of description is like that applied to a stratum by the geologist. By definition, the strike of a tabular vein or ore bed is the direction in azimuth of the line marking its intersection with a horizontal plane; the dip of the plane of the vein or bed is its angle of inclination measured from the horizontal down the slope of the plane and normal to the strike. A fissure vein may thus be said to strike N. 20° E., with dip 50° S.E., its attitude being thus defined.

Within an otherwise barren fissure vein there may be a richer part, the shoot. If large, the ore shoot is a bonanza, if small, a pocket. If dimensions are given for such shoots, the longest measurement in the horizontal plane is the stope length ("stope" being the cavity ultimately left when the ore body has been mined out), the longest dimension directly down dip is the stope depth and the smallest in the horizontal plane is the stope width or thickness. If the ore body is chimneylike, cylindrical or relatively long for its width, the miner may refer to the dimension down dip along its longest axis as the pitch length.

Exploration for Ore Deposits.—Ore deposits are sought by means of three related methods—geological, geophysical and geochemical. Geological exploration is dependent upon a knowledge of the basic geology of the terrain in which the ore is being sought. This may be carried to varying levels of detail. For example, if exploration were contemplated in Mexico, general geologic facts and previous experience indicate that search for copper might

be pursued with best hope for success in the northwestern part of the country, especially in Sonora; search for lead and zinc in the Mesa Central or the Sierra Madre Oriental; and for precious metals in the andesitic lavas of the canyon region, designated by some the Sierra Occidental. Thus are defined certain metallogenic provinces, characterized by ores rich in a specific group of metals, as though the deeper, molten part of the earth in each province had distinctive components. The ancient rocks of the Pre-Cambrian shield of eastern Canada bear little zinc or lead but have produced much gold, nickel and copper, suggesting, by this linkage of their age with certain metals, that specific ore types characterize certain periods of the earth's history, distinguishable as metallogenic periods; this concept can be applied also to sedimentary ores such as the siliceous banded iron ores which are virtually confined to the Pre-Cambrian.

The problem may, instead, be one of greater detail. When reason to expect ore in a small area or a mine exists, where shall search be especially pressed? Placer gold may be followed upstream till it stops; the outcrop of the vein from which it was derived should be on the stream bank or in the drainage basin near at hand. Principles of structural control may be used; given ore-bearing fissures, the richest and largest shoots are generally near intersections of two fissures. If present along a vein, ore is commonly found where strike or dip changes abruptly. Ore is common in smaller folds above dome-shaped intrusions. It is generally richest where a mineralized vein passes from shale to limestone, especially under capping beds of shale or other impervious or insoluble rock.

With progressive exhaustion of ore bodies that crop out, methods are continually sought by which subtler criteria can be used to find buried ore. The surface residue, especially the limonitic outcrop (gossan, "iron hat"), has been studied (Augustus Locke, Roland Blanchard, P. F. Boswell, 1926 *et seq.*) in an attempt to establish colours, textures and the like characteristic of the deeper, primary ore; also gossan is analyzed for traces of deeper elements. Alteration halos marking changes produced by solutions accompanying ore deposition have been recognized for some time as clues; these halos are distinguished by their predominant minerals—tourmalinization, albitization, epidotization, sericitization, kaolinization, sideritization and dolomitization. Special types are greisenization (bleaching and sericite development in an alkali-rich igneous rock), propylitization (the development of certain greenish minerals in intermediate to basic igneous rocks) and the widely distributed development of claylike minerals (argillization, T. S. Lovering, G. M. Schwartz and P. F. Kerr *c.* 1944) and of silica (silicification) which received particular attention after 1940.

Geophysics (*q.v.*) affords methods also increasingly useful. Many iron ores and some others are magnetic; the compass and dip needle (a vertically suspended magnetic needle) have been used for over a century in search of such ores. Lately modified forms of such instruments (the "flying magnetometer") have been flown over promising terrain. Electric methods depend largely on the electric potential developed as ore bodies oxidize. Conductivity of ore minerals, generally higher than that of gangue, is studied with the aid of sensitive current measurements. Gravity anomalies may be a guide to ore. Uranium-rich ores give counts with a Geiger counter, and many ores, especially those of tungsten, fluoresce with characteristic colour and may thus be sought in the dark.

Tools developed by mid-20th century were geochemical ones. Careful analyses give evidences of ore by traces of the ore elements, whether the traces are in the rock outcrop, the residual soil or in growing plants rooted in that soil, or in water draining across it.

These methods have as object narrowing down the area to be explored. Once thus narrowed, the area may be explored at depth by drilling with auger, churn drill or diamond drill, by pit-hole sinking, tunnelling or shaft sinking. Diamond drilling furnishes a solid cylindrical core (if recovery is good), which can be geologically studied and provides a sample for chemical analysis as well.

Evaluation of Ore Deposits.—Geologists and mining engineers are required at times to evaluate an ore body, quite aside from the equipment that may be on the ground. For this purpose the deposit must be sampled, usually by making a cut into a clean face of typical ore and analyzing (assaying) the material thus obtained. Systematic, large-scale sampling repeats the process at regularly spaced intervals and seeks a weighted average to obtain the grade of the ore. The total volume of the ore is then computed using measured or inferred dimensions. The specific gravity of the ore is obtained, the weight per unit volume determined from this and the total tonnage derived by multiplication. The case is simple if the ore body is a tabular one, such as a simple vein of fairly constant thickness, or a replacement body in a stratum, or a sedimentary ore bed. For such cases E. F. Burchard recommended the formula:

$$\text{Total tonnage} = \frac{\frac{1}{2}(T+t) \times L \times D \times R}{\text{cu.ft. per ton}}$$

in which T is average thickness of ore bed (or vein) at outcrop, t is minimum workable thickness, L is length of outcrop, D is distance from outcrop at which thickness of ore becomes t and R is the percentage of recoverable ore. In complex ore bodies changing in richness and volume from place to place, the body is divided, for the purpose of computation, into geometrical units small enough to be essentially constant in width, thickness and composition; the tonnage and grade of each such unit is then separately determined to give a total for the deposit as a whole. The most comprehensive estimates require consideration of such diverse factors as future metal prices, rates of exhaustion (depletion), probable tax assessments, mining, milling and transportation costs, and even such matters as labour sources, pertinent tariff policies and political and economic stability of the country where the mining is to be carried out.

Special attention in the 20th century has been given to the role of mineral deposits in international affairs and in the economics of development, and much literature dealt with this broad subject, especially after World War I.

ORE DRESSING is the art of treating crude ores and mineral products by mechanical means to separate the valuable minerals from the worthless constituents in the crude material. The term "ore dressing" at one time referred only to processes employed in treating ores containing valuable metals such as gold and silver, but as these processes were applied more and more to the recovery of nonmetallic minerals it was also used to describe the methods for treating such materials as graphite, sulphur, mica, feldspar, asbestos and fluorspar. The term "mineral dressing" is becoming widely used instead of "ore dressing" because of its broader meaning. Usually the two terms are considered to be synonymous, but sometimes mineral dressing is intended to include other branches of metallurgy and coal preparation whereas ore dressing always refers to methods of separation of solid inorganic minerals from each other without effecting substantial chemical changes.

The need for ore dressing to produce enriched products or concentrates from low-grade ores arises from the fact that most metals and valuable minerals do not occur in nature in such a form as to be usable directly. The common base metals copper, lead and zinc seldom comprise more than a few per cent of the total rock from which they must be extracted and usually occur combined chemically with other elements. These metal-bearing com-

pounds must eventually be subjected to a chemical treatment to break up the chemical union and liberate the metallic elements. The processes employed to accomplish the chemical separations are expensive as a rule, and the cost depends largely on the bulk of material treated. Thus it would cost as much to smelt a ton of copper ore containing 1% copper as to smelt a ton of concentrated copper ore with 30% copper, and the amount of copper produced in the first case would be only one-thirtieth as much as in the second. It is economically impossible to smelt a copper ore of 1% but, by using relatively cheap ore-dressing processes to make 30% copper concentrates for smelting, the 1% ore can be utilized economically.

Ore dressing is the first process which most ores undergo after they are dug from the ground. It may consist of very simple operations such as washing with water and hand sorting to select the richer ore pieces, or it may involve much more complicated processes using elaborate equipment to effect the separations desired. The primary operations in ore dressing are comminution, or crushing, and concentration, but there are many other important operations involved in modern ore-dressing plants, such as sizing and classification, settling and filtering, drying and heat treating, and agglomerating or pelletizing.

Comminution.—Some ores occur in nature as mixtures of separate mineral particles that are not attached to each other and require no crushing or breaking apart. Examples of this type of ore are the placer deposits found in stream and gravel beds where the ore mineral is native gold or perhaps precious stones such as diamonds or emeralds, or perhaps it is simply gravel to be utilized in concrete highways. These materials are mined and the valuable constituent concentrated directly without crushing, but important as the minerals found in such condition may be they represent only a small portion of the ores treated throughout the world for their mineral content. By far the greater part of the ores mined consist of hard and tough rock masses that must be crushed to free the valuable minerals. This operation is called comminution and sometimes includes the breaking down of the ore from huge boulders to fine powders depending upon the fineness of dissemination of the mineral particles.

Comminution of ores is customarily done in three steps: primary or coarse crushing, secondary or fine crushing and grinding. Primary crushing is usually accomplished with jaw or gyratory crushers. Jaw crushers consist of two steel "jaw plates" one of which is stationary and the other movable. Rock fed between the plates is mashed by the action of the movable jaw and reduced to a size small enough to be taken by the following or secondary crusher. Gyratory crushers are essentially a fixed crushing surface, in the form of an outer steel shell, and an inner spindle that is made to gyrate or to rotate, thus alternately receding from and approaching all the points on the outer shell. These machines in their largest form are capable of taking rock masses up to six feet in their longest dimension and reducing them to as small as one inch in size.

Secondary crushers are numerous, the more commonly used ones being rolls, cone crushers and rod mills. These machines customarily receive rock one to three inches in size and reduce it to about one-fourth or one-eighth inch. Rolls crushers consist of a heavy steel frame on which are mounted two cylindrical steel rolls. These rolls are driven so that they rotate toward each other in the same manner as the rollers on a clothes wringer operate. Rock or ore fed between the moving rolls from above is nipped, crushed and discharged below the rolls. Cone crushers consist of an inverted bowl-shaped steel crushing surface within which is gyrated a conical crushing head. The conical crushing head is mounted on a shaft and is gyrated by means of a long eccentric which is driven by a gear and motor assembly similar to those used on the larger gyratory crushers. Rod mills formerly were used only for relatively fine grinding but became popular as secondary crushers because of their high capacity and low maintenance costs. They are cylindrical-shaped steel shells loaded with steel rods and rotated about their horizontal axis. Ore and water are fed into one end of the shell, and the ore is crushed by the tumbling heavy rods within the shell. Rod mills are always made of a length greater than their diameter in order that the rods will not become tangled inside the mill.

There is little difference between grinding and crushing except that crushing usually refers to breaking coarse material, and grinding applies to relatively fine material. Originally grinding referred to that method of comminution which involved a heavy object being dragged or rolled over the material being ground. Mortar and pestle grinding is an example of this type of grinding, and there are still some of the early-type commercial machines in use that employ this principle. The arrastra or drag-stone mill grinds the ore by dragging flat stones around a circular stone floor; roller mills employ heavy rollers revolving about a central shaft on a circular ring; buhrstone mills consist of two flat circular stones, either one of which may rotate or they may both rotate in opposite directions with grinding taking place between the stones. However, modern ore-dressing plants almost always employ rotating cylindrical mills for fine grinding. A mill containing iron or steel balls for the grinding medium is called a ball mill; if it contains rods it is called a rod mill, and if it contains lumps of rock, ore or flint pebbles it is a pebble mill. These mills may be operated either wet or dry depending on the character of the ore or subsequent ore-dressing processes to which the ore is to be subjected.

Concentration.—The act of separating the valuable minerals of an ore from the worthless matter (gangue) into one or more enriched or concentrated products is called concentration. In ore dressing this is possible because of the difference of certain properties of the mineral particles. The simplest form of concentration is hand picking, which is used occasionally in modern plants to remove either rich material or waste material by hand from a moving table or conveyor belt. This operation employs the difference in colour or lustre of the lumps of rock so that the picker may distinguish the wanted from the unwanted material. Differences in the density of minerals permit separation by various methods of gravity concentration; magnetic properties are the basis for separation by magnetic methods; electric properties govern the electrostatic separation of minerals, and surface properties are used to effect the almost magic separations accomplished by flotation.

The feed to a concentration process consists of ore crushed and ground to a suitable size and is called the heads. The enriched product derived from the process is known as concentrates, and the waste or unwanted material is called tailings. A third product of the concentration treatment may be produced which requires further treatment before it can be resolved into concentrates and tailings. This product is called a middlings and, theoretically at least, consists of valuable and gangue minerals which are still locked together. When such a fraction is produced it is returned to the grinding equipment for further comminution and retreatment.

In addition to the simple process of hand picking there are other seemingly crude but effective methods of concentration which are widely used throughout the mining industry. For example, many ores such as those containing nodular manganese and iron minerals occur in a matrix of clay. Often the manganese and iron nodules require only washing with water and vigorous agitation to separate them from the soft clay. This results in greatly enriched concentrates which may be utilized by the iron and steel industry. Another simple concentrating device is an ordinary screen which may be used on many ores where the valuable mineral is either finer or coarser than the size of the openings in the screen. The hardness of minerals is sometimes utilized to effect separations by screening. This may be accomplished by first grinding the ore in a ball mill so that the softer minerals are differentially ground, and the harder minerals almost retain their original size. Simple screening of the differentially ground material results in the production of concentrates of the harder mineral on the screen while the softer material goes through the screen.

Gravity concentration processes have been practised by ore dressers to obtain mineral concentrates from the earth throughout the history of mankind. Probably the first gold ever seen by man was obtained from some ancient stream bed by some form of pan-

ning that was not much different from that used by prospectors in modern times. The miner's gold pan is simply a device to concentrate heavy minerals in the bottom of the pan while the lighter, worthless minerals are washed off the top. The mechanical jig is a development of the gold pan that utilizes the faster settling rate of heavy minerals through a semistationary bed of crushed ore in water. Essentially a jig is an open box with a perforated bottom through which pulsating water currents are forced. Crushed ore fed into the top of the box is stratified by the action of the water currents, with the heavier minerals settling to the bottom. If the heavy minerals are fine enough, they pass through the perforated bottom and are discharged intermittently through a spigot. If they are too coarse to pass through the perforations, they are removed continuously through a cup or pocket on top of the perforations.

Shaking tables are gravity concentration devices used to treat material too fine for jigging. They consist of a tablelike surface inclined slightly from the horizontal and are operated with a reciprocating action that shakes the table in the direction of the long axis. Fine ore and water are fed to the upper corner of the table and flow across the deck which has shallow riffles running the full length of the table. The reciprocating action of the table causes the heavy minerals to move to the end of the table, while the lighter minerals are washed by the water over the side of the deck. Shaking tables are called sand tables or slime tables, depending upon the size of the material that they treat.

Heavy-medium or sink-float separation processes are concentration methods that depend on the buoyant power of suspensions of fine heavy solids in water. Separating vessels are usually in the shape of a stationary cone, a revolving drum or a stationary tank with a revolving screw conveyor to remove the concentrates. The vessel is filled with a mixture of finely divided particles of some heavy material such as ferrosilicon, magnetite or galena and water. The mixture acts as a fluid with an apparent specific gravity lower than that of the mineral to be concentrated but higher than that of the gangue minerals. Crushed ore fed into the liquid-solid mixture separates into a sink or heavy product and a float or light fraction. The sink product is removed continuously from cone separators by pumps and from drum and screw separators by means of suitable conveyors. The float product overflows the top of the vessel in which the separation is made and both products are separated from the heavy medium by screening and washing with water. The treatment is applicable only to ores coarser than about one-eighth inch because of the relatively high viscosity of the heavy medium. The settling rate of fine particles in a viscous liquid or suspensoid medium is too slow to permit rapid separation, and other gravity concentration methods must be used for the finer portion of an ore.

Gravity concentration processes for treating fine sands include spiral separation which employs a spiral trough with a curved bottom. When fed with a water-sand mixture, the dilute pulp flows by gravity from the top of the spiral to the bottom. The lighter minerals, usually quartz and feldspar, are more easily suspended by the water and are washed to the outside of the spiral, while the heavier particles tend to cling to the bottom and inside of the trough. Ports or outlets are spaced along the bottom of the spiral for removal of heavy concentrates while the lighter tailings are discharged at the lower end of the spiral. Shaking tables accomplish the same separations that spirals do, but require more floor space and have more moving parts. Hydrocyclones, also known as Dreissen cones or Dutch State Mines cyclones, may be used in conjunction with a heavy-medium suspension to effect separations of heavy minerals in fine sizes. The hydrocyclone consists of a cone-shaped vessel in which a separation is made based on the principle of the vortex. A dilute ore pulp is pumped tangentially into the cone near the top with a heavy medium and the heavier ore particles find their way to the bottom of the cone while the lighter gangue minerals are removed at the top.

The foregoing processes involve concentration of ores with water, but there are equivalent processes employing air as the separating medium. Pneumatic jigs and tables operate on the same principles of gravity separation as wet jigs and tables but find use in desert regions where water is scarce and on ores that are best treated dry, such as asbestos, which depends upon the light, fluffy nature of the mineral for efficient concentration.

Magnetic separation is an efficient means for concentrating many minerals which contain iron. The mineral magnetite is both heavy and strongly attracted by a magnetic field and may be separated from its gangue minerals by either gravity concentration or magnetic methods, but magnetic separation of magnetite is so highly efficient that it is almost invariably used to concentrate the mineral rather than other, perhaps less complicated, processes. Originally dry magnetic pulleys were the only separators used for concentrating magnetite, but wet separators were found to produce much richer concentrates.

Minerals such as garnet, ilmenite, wolframite and haematite are not as strongly magnetic as magnetite but are sufficiently attracted by a powerful magnetic field to permit separation from completely nonmagnetic minerals such as quartz, feldspar, rutile and zircon. A number of specially designed magnetic separators were found suitable for concentrating these weakly magnetic minerals. Among them are the induced-roll separator and the crossed-belt separator, both of which are highly efficient and widely used. They differ from each other largely in the manner of conveying the ore particles through the magnetic field. The induced-roll machine utilizes a revolving roll to carry the ore stream through the field, the magnetic particles adhering to the roll while the nonmagnetic particles are thrown by centrifugal force away from the roll. The crossed-belt separator, as the name implies, consists of a conveyor belt which carries the ore through the field and a second belt crossing under a magnet above the first belt and at right angles to it; magnetic particles are attracted upward toward the magnet and are removed to the side by the travelling belt, while the nonmagnetic particles remain on the first belt and are discharged at the end of the machine.

Electrostatic separation is a concentration method that utilizes the force of an electric field to effect separations between minerals with different electrical properties. It is based on the phenomenon of attraction between unlike electrical charges and repulsion between like charges. It is particularly applicable to the separation of some nonmetallic minerals although it may be applied to metallic minerals with equal success. It is the only process that proved successful for separating zircon from rutile, these being commonly found associated in beach sand deposits.

Flotation is perhaps the most important concentration process in the mineral industry in that more ore is treated by this method than by any other. As applied to ore dressing, the process dates back to ancient times when the Greeks reportedly used feathers dipped in pitch to recover gold from the mud of a lake, but large-scale modern use of flotation did not come about until after 1924 when the use of xanthate, to collect metal sulphides in a froth, was patented.

The flotation process depends upon the ability of the ore dresser to wet selectively some mineral particles while other minerals remain unwetted and adhere to air bubbles which float to the surface and are removed as a concentrate in the froth. Certain minerals, such as graphite, talc and sulphur, are called self-floating because of their natural tendency to resist wetting by water, but most minerals require coating with a water repellent to render them floatable. Coating the finely ground mineral particles is accomplished by agitating the mixture of ore, water and suitable chemicals in a conditioner for a short time, during which the chemicals react with the elements at the surface of the particles to form a new surface which is more water repellent than the original surface. Minerals that naturally tend to resist wetting may be treated so that their surfaces will be wetted and they will sink in the water and not be floated with the concentrates. Flotation is most commonly used to concentrate copper, lead and zinc minerals from their ores because of the ease with which they are floated or not floated as the case may be. These minerals often occur together and the ore dresser is called upon to separate them from each other as well as from the gangue minerals. By using suitable chemicals it is possible to float copper, lead and zinc minerals selectively from each other by preventing the flotation of

all minerals, except those containing lead, then floating only the copper minerals and finally only the zinc minerals. This ability of the ore dresser to modify the floatability of minerals at will made possible many seemingly magical separations that are common practice in modern mills. In fact it can be said that any two minerals may be separated by flotation if one contains a substantial amount of one element that is absent in the other.

Sizing and Classification.—All ore-dressing concentration processes require that the ore be sized to a certain degree. Often it is the size to which the ore must be ground before the valuable minerals are unlocked that governs the process that will be used to concentrate those minerals. Machines, used to assure grinding to at least unlocking sizes, are called sizers or classifiers. Screens are perhaps the simplest devices used to size ores, and they are widely used in a variety of forms. Fixed screens, for coarse sizing, consist of parallel bars, punched plates or coarsely woven wire. Trommel screens are cylindrical screens revolving slowly about their horizontal axes; vibrating screens are plane surfaces of woven wire cloth which are rapidly vibrated by mechanical or electrical means; and shaking screens are slightly inclined plane surfaces of wire cloth shaken endwise or sidewise. All screens may be used with or without water and some modern screens are heated either by electric current or hot air. Heated screens are less inclined to become blinded by sticky material and thus have greater capacity than unheated ones. Classifiers are made in numerous forms and may be operated either wet or dry. Hydraulic classification depends upon the different settling rates in water of grains of mixed sizes. The water in a classifier may be either in motion or substantially at rest. Air classification is equivalent to the wet operation except that air is used as the medium instead of water. Centrifugal classifiers, wet or dry, are devices that utilize centrifugal force to effect separations between coarse and fine particles.

Settling and Filtering.—Settling or thickening is a term applied by the ore dresser to the process of removing water from a dilute mixture of fine ore and water so that a relatively thick pulp results. Most ore-dressing processes require large amounts of water and the resulting concentrates and particularly the tailings are extremely dilute. The first operation in separating the solids from the water is usually carried out in thickeners. These are large tanks in which the fine solids are allowed to settle. Chemicals are sometimes added to increase the settling rate of the solids. Feed to thickeners usually contains from 5% to 20% solids, and the discharge, which is pumped from the bottom of the thickener, varies from about 40% to 80% solids. Thickened pulps may be further dewatered by filtering. Filters for ore-dressing plants are usually rotating cylinders covered with a porous fabric through which the water is drawn by means of a vacuum under the cloth. Such machines are called vacuum filters, and there are numerous other forms and types of filtering devices.

Drying and Heat Treating.—Dryers for ores and concentrates consist of some form of container and a means to apply heat to the wet material within the container. Most commonly used dryers are rotary kilns which are slightly inclined rotating cylinders with a burner at one end or the other. Wet ore is fed continuously to the upper end of the cylinder while the dry material is discharged at the lower end. Infra-red lamps are sometimes used to dry small quantities of concentrates, and many kinds of dryers have found use on special types of ores. Roasting is sometimes used in ore-dressing plants to change the form of some mineral in the ore so that it may be more easily concentrated. Roasting of pyrite, for example, to drive off sulphur and render the mineral magnetic is carried out in roasters of various types. Roasting sometimes causes a mineral to expand or decrepitate, as in the case of vermiculite which expands and spodumene which breaks into small particles, thus making it more readily separable from unaltered minerals.

Agglomeration.—Some ores, particularly those of iron, chromium and manganese, which are smelted in blast furnaces cannot be utilized as fine particles. They must be agglomerated in some manner so as to form large, tough lumps of material suitable for smelting. This process, variously called sintering, agglomerating, nodulizing, pelletizing and briquetting, may be carried out by fusing the material at high temperature, as is done in sintering and nodulizing, or by mixing a binder such as starch, molasses or bentonite with the fine ore and heating or applying pressure to the mixture. (*See* also AMALGAMATION; CYANIDE PROCESS.)

OREGON, popularly known as the "Beaver state," is one of the northwestern states of the United States of America. Its capital is Salem. It lies on the Pacific slope between approximately 42° and 46° 18′ N. and 116° 33′ and 124° 32′ W. It is bounded on the north by Washington from which it is separated in part by the Columbia river and in part by the 46th parallel; on the east by Idaho, from which it is separated in part by the Snake river; on the south by Nevada and California; and on the west by the Pacific ocean, upon which it has a tidal shore line, omitting islands, of 429 mi. It has an extreme length east and west of 375 mi., an extreme width north and south of 290 mi., and a total area of 96,981 sq.mi., of which 666 sq.mi. are inland water surface. The origin of the name "Oregon" is unknown. The first known use of the word was by Maj. Robert Rogers in 1765 in his plans for an exploring expedition to the northwest coast. He applied it to a river flowing into the Pacific ocean of which he had heard. Such a river was discovered in 1792 and named "Columbia," but the name "Oregon" was given to the entire territory drained by this river. Several states were created out of this territory and only the present area retains the name.

Of the total area of approximately 62,000,000 ac. the federal government at mid-20th century held title to about 32,600,000 ac., consisting largely of public domain used for grazing, national forests, revested forest lands and Indian reservations.

Physical Features.—The coast of the state extends in a general north and south direction for about 30 mi. and consists of long stretches of sandy beach broken occasionally by lateral spurs of the Coast range and by bays into which coastal streams empty. Parallel with the coast and with its main axis about 20 mi. inland is an irregular chain of mountains known as the Coast range. The range is irregular, with a maximum elevation of 4,097 ft. (Mary's Peak). Several rivers, among them the Nehalem, Umpqua and Rogue, cut their way through the Coast range to reach the ocean. For the northern two-thirds of its length in Oregon the Coast range is bordered on the east by the Willamette valley, which is about 150 mi. long and 30 mi. wide, and is the most thickly populated portion of the state. In the south the Coast range merges into the complex group designated as the Klamath mountains, lying partly in Oregon and partly in California, and extending from the northern extremity of the Sierra Nevada to the sea. A number of ridges in the group bear local names, such as the Rogue river, Umpqua and Siskiyou mountains. The Cascade mountains, which cross the state from north to south about 100 mi. inland, form the predominant physical feature of the state. They are the product of succeeding periods of vulcanism and folding. Some of the peaks are cones of extinct volcanoes, with glaciers on their slopes. Highest point in the state is Mt. Hood (11,245 ft.); other peaks in the Cascades are Mt. Jefferson (10,495 ft.), Three Sisters and Diamond peak.

The Cascade mountains divide the state topographically into two sharply contrasted parts. West of this range the country exhibits a great variety of surface structure and is humid and densely wooded; east of the range it consists of a broken tableland, arid or semiarid, with a general elevation reaching 5,000 ft. This eastern tableland, though really very rugged and mountainous, has few striking topographic features when compared with the more broken area to the west. In the northeastern part of this eastern plateau lie the Blue mountains, which have an average elevation of 6,000 ft. and decline gradually toward the north. A southwestern spur,

about 100 mi. in length, and the principal ridge together enclose on several sides a wide valley drained by the tributaries of the John Day river. Draining the eastern slopes of the Cascade range for the northern two-thirds of its length and flowing into the Columbia a few miles west of the mouth of the John Day river is the Deschutes river, flowing through a valley less arid than the plateau region to the southeastward. Southeast of the Deschutes river and south of the Blue mountains lies the great basin region. In Oregon this area extends from the Nevada boundary northward for about 150 mi. and embraces an area of about 18,500 sq.mi. All of its streams lose their water by seepage or evaporation. Many of the mountains within the basin region consist of great faulted crust blocks, with a general north and south trend. One face of these mountains is usually in the form of a steep palisade, while the other has a very gradual slope. Between these ridges lie level valleys whose floors consist partly of lava, partly of volcanic fragmental material, partly of detritus from the bordering mountains.

Some large permanent lakes occupy troughs between faulted blocks in southern Oregon, among them Malheur and Harney lakes in Harney county and Lake Abert, Warner and Summer lakes in Lake county. All of these are salt and shallow, shrinking to small proportions in the dry season. East of the Steens mountains, besides a number of small alkaline lakes, is a playa or mud flat, known as the Alvord desert, which in the spring is covered with 50 to 60 sq.mi. of rain water only a foot or two deep.

In the northwestern quarter of the basin occupying an area 100 mi. long and 60 mi. wide is a part of Oregon's high desert. Its surface consists of pumiceous soil and earth blown from the semiarid depressions once occupied by lakes that formed in troughs between fault-block mountains. From this plateau surface arise ridges and mountains created by earth faulting, and weathered buttes that are remnants of volcanic cones. There are no surface streams in the area except a few that are seasonal. Semiartesian water is pumped from wells in the Fort Rock valley, and shallow excavations in the northern part of the area provide water for livestock. A heavy growth of sagebrush covers most of the region and western junipers are abundant.

Southwest of the basin and draining the southern third of the eastern Cascade slopes is the Klamath valley, containing Upper Klamath lake, drained by Klamath river. Near the northwestern boundary of Klamath county is Crater lake, whose surface is 6,160 ft. above the sea. This lake lies in a great pit or caldera created by the wrecking in prehistoric times of the volcano Mt. Mazama, which according to geologists once had an altitude of about 14,000 ft. above the sea and 8,000 ft. above the surrounding tableland. The upper portion of the mountain was blown off or fell inward, possibly because of the withdrawal of interior lava; and a craterlike rim or caldera was left, rising 2,000 ft. above the surrounding country. The lake is 4 mi. wide and 6 mi. long, has a depth in some places of nearly 2,000 ft. and is surrounded by walls of rock from 500 to 2,000 ft. high. In spite of its great elevation the lake has never been known to freeze, and though it has no visible outlet its waters are fresh.

East of the great basin and the Blue mountains is the region tributary to the Snake river. The southern half, drained by the Owyhee river, is much like the great basin, being arid and plainlike in character. North of the Owyhee the chief tributaries of the Snake are the Malheur, Burnt, Powder and Grande Ronde rivers flowing through small but beautiful and fertile valleys.

In the northeastern corner of the state are the Wallowa mountains, an upthrust of granite and marble, very scenic, with sharp peaks rising to the height of 10,000 ft., and numerous lakes. Here at the border of the state the Snake river goes through a mile-deep canyon (Hell's canyon), with near-vertical walls, one of the deepest gashes on the surface of the earth.

Climate.—Along the coast and in the western valleys the climate is mild, uniform and relatively humid except during the warmer summer months. Air masses moving across the higher Cascades lose, by precipitation, a considerable part of their moisture causing the eastern two-thirds of the state to be dry with much greater temperature extremes. Along the coast the normal annual precipitation is near 75 in., increasing to as much as 130 in. at some of the higher elevations in the Coast range. In the western valleys it ranges from about 18 in. in the Medford area to as much as 50 in. in the northern Willamette valley. This increases to between 75 and 90 in. on the upper west slopes of the Cascades, then declines sharply moving down the east slopes. On the eastern valley floors yearly normals vary from less than 8 in. to slightly more than 25 in., with those for 80% of the area lying between 9 and 14 in.

Temperatures along the coast never go as low as 0° F. and only rarely reach 100°. In the Willamette valley a few degrees may be added to each extreme, but even here temperatures of zero or lower have been recorded only a few times, and those above 90° occur on an average of only six to eight times a year. There is only a range of 15° (45°–60°) between the coast average mean January and July temperatures. In the Willamette valley this ranges from 38° in January to near 66° in July. In the Rogue river valley of southwest Oregon the July mean is about 5° higher and the occurrence of temperatures above 90° is about seven times as great as in the Willamette. East of the Cascades temperatures have been recorded as low as −54° and as high as 119°. These, however, are the extreme conditions. The normal mean January temperature is 25°–28° in valleys of the southeast and 29°–33° in those of the northeast. Average July means in central Oregon range between 65° and 70° while those of the extreme eastern area are between 70° and 78°.

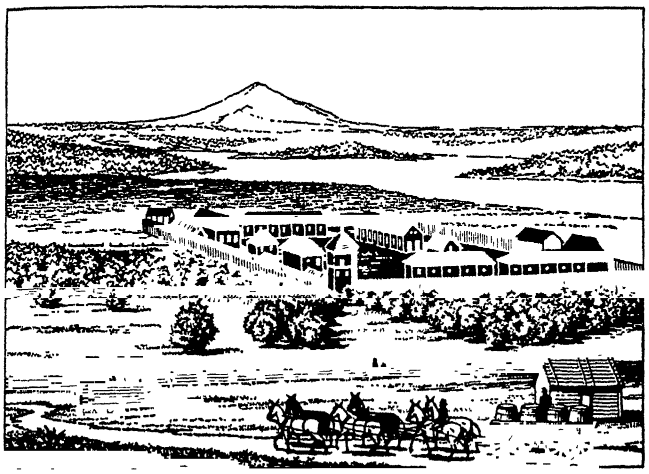
Snowfall at many coastal stations averages only about an inch a year; in the Rogue river valley the average is near 20 in.; in the Willamette valley from 6 to 13 in.; while at elevations of 6,000 ft. on Mt. Hood a short-time record indicated an average annual fall of approximately 465 in. Except at higher elevations eastern stations have between 16 and 20 in. of snow each winter.

Winter relative humidities average between 80% and 90% in western Oregon and near 70% east of the Cascades. Average July humidities range between 55% and 65% in the west and near 40% in the east, though in both areas humidities in the low 20s are common during periods of highest temperatures.

History.—The Spanish pilot, Bartolomé Ferrelo, who in 1543 made the farthest northward voyage along the Pacific coast recorded in the first half of the 16th century, may have sighted the shores of Oregon. So also the famous English captain, Sir Francis Drake, who in 1579 coasted these shores seeking a route home by a northwest passage is supposed to have reached a point near 43° lat. before giving up the search and turning westward across the Pacific. In 1603 the Spaniards Sebastián Vizcaíno and Martin d'Aguilar also passed 42° lat., D'Aguilar claiming to have reached a point of land near 43° which he called Cape Blanco. The Spanish, however, were too much interested in the profitable trade between their colonies and the far east to give much attention to northwest exploration, and it was not until 160 years later that fear of Russian and English encroachment caused them to send out further expeditions. In 1774 Juan Pérez was sent out with orders to proceed to 60° lat. He turned back at 54° but was the first to sail along the entire coast line of the Oregon country. The following year Bruno Heceta commanded another expedition which near Point Grenville made the first landing in the region. They erected a cross and in formal ceremony took possession for Spain.

The Spaniards made no effort to colonize northwestern America or to develop its trade with the Indians, but toward the end of the 18th century the traders of the great British fur companies of the north were gradually pushing overland to the Pacific. Upon the sea, too, the English were not idle. Capt. James Cook in March 1778 sighted the coast of Oregon in lat. 44°, and examined it between 47° and 48° in the hope of finding the Straits of Juan de Fuca described in the Spanish accounts. Soon after the close of the Revolutionary War U.S. merchants began to buy furs along the northwest coast and to ship them to China to be exchanged there for the products of the east. It was in the prosecution of his trade that Capt. Robert Gray (1755–1806), an American in the service of Boston merchants, discovered in 1792 the long-sought river of the west, which he named the Columbia, after his ship. By the discovery of this river Gray gave to the United States a claim to the whole territory drained by its waters.

Land exploration soon followed these discoveries along the coast. Alexander Mackenzie, in the service of the North West company, in 1793 had explored through Canada to the Pacific coast in about lat. 52° 20′ N., and Meriwether Lewis and William Clark, U.S. explorers acting under the orders of Pres. Thomas Jefferson, in 1805–06 had passed west of the Rocky mountains and down the Columbia river to the Pacific ocean. Both British and U.S. adventurers



BY COURTESY OF THE UNION PACIFIC SYSTEM
FORT VANCOUVER OF THE HUDSON'S BAY CO. ESTABLISHED IN 1815, AFTER A SKETCH MADE BY STANLEY IN 1854

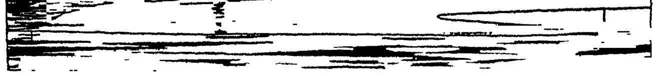
were attracted to the region by the profitable fur trade. In 1808 the North West company had several posts on the Fraser river, and in 1809–11 they built others south of the 49th parallel. In 1811, also, the Pacific Fur company, under the guidance of John Jacob Astor of New York, founded a trading post at the mouth of the Columbia which was called Astoria, and set up a number of minor posts on the Willamette, Spokane and Okanogan rivers. On hearing of the war between England and the United States, Astor's associates, deeming Astoria untenable, sold the property in 1813 to the North West company. The British took formal possession and renamed the post Fort George.

Soon after the restoration of peace between England and the United States there arose the so-called "northwestern boundary dispute" or "Oregon question" which agitated both countries for a generation and almost led to another war. The United States was willing at the time to extend the northwestern boundary along the 49th parallel from Lake of the Woods to the Pacific, but to this the British government would not consent, so in 1818 both nations agreed to a "joint occupation" for ten years of the country "on the north-west coast of America, westward of the Stony (Rocky) mountains." By treaty the following year Spain waived its claim to the territory north of 42° in favour of the United States, and in 1824 Russia likewise agreed to make no settlements south of 54° 40′. In 1827 the agreement of 1818 for joint occupation by Great Britain and the United States was renewed for an indefinite term, with the proviso that it might be terminated by either party on 12 months' notice. For the next three decades the history of Oregon was concerned mainly with British fur traders and U.S. immigrants. The Hudson's Bay company absorbed its rival, the North West company, in 1821 and thus secured a practical monopoly of the trade of the Oregon region. Its policy was to discourage colonization, in order to maintain the territory in which it operated as a vast preserve. The company sent to the Columbia river as its governor west of the Rocky mountains John McLoughlin, who ruled the vast empire firmly and wisely for 22 years and became known affectionately as the "Father of Oregon." His capital was at Fort Vancouver which he built on the north bank of the Columbia opposite the mouth of the Willamette river. In 1829 he also built an establishment at the falls of the Willamette which determined the site of Oregon City. Though it was against the company's interests he generously aided the U.S. colonists who later came to the region and later in life, after U.S. government was extended over the country, himself became a citizen of the United States.

The elderly employees of the company were urged by McLoughlin, when they wished to retire from active service, to settle with their families in the Willamette valley. There were a number of these settlers, mostly French Canadians, there by 1835. In 1834 Jason and Daniel Lee arrived from the United States and founded Methodist missions in the Willamette valley. In 1837, 20 more missionaries arrived and a branch mission was opened at The Dalles. In 1838 Jason Lee started overland for the states, and his lecturing and preaching not only raised money for the mission but aroused great interest in Oregon, with the result that the U.S. element was increased in 1840 by 50 more arrivals by sea. In 1842 the first immigrant train over the Oregon trail, headed by Elijah White and piloted for part of its way by Thomas Fitzpatrick, arrived. The following was the year of the "Great Migration" when nearly 900 men, women and children likewise followed the trail and settled in the Willamette valley. After this the flow of immigrants over the Oregon trail steadily increased, about 1,400 arriving in 1844 and 3,000 in 1845. The U.S. settlers started a movement for the immediate and permanent settlement of the Oregon dispute. In 1843 they had established for themselves a provisional government, but settlement and business undertakings were held back until their future rulers and the nature of their permanent government were settled. The western states rallied to their support with the result that the Democratic national convention in 1844 declared the title of the United States to "the whole of the Territory of Oregon" to be "clear and unquestionable," and the party made "Fifty-four forty or fight" a campaign slogan. Upon the success of the party, negotiations were entered into which resulted in a compromise treaty (1846) fixing the boundary between Oregon and British possessions at its present position, and giving the United States complete title to all land to the southward.

Territorial status and a territorial government were delayed until 1848 because of opposition from the slavery element in congress. As then constituted the territory included the present states of Oregon, Washington, Idaho and parts of Montana and Wyoming. Its area was reduced in 1853 by the creation of the territory of Washington. The discovery of gold in California drew many Oregon settlers to that country in 1848–50, but this exodus was soon offset as a result of the enactment by congress in 1850 of the Donation Land act by which settlers in Oregon were able to obtain large tracts of land free of cost. The number of claims registered under this act was more than 8,000.

In 1857 the people voted for statehood; in the same year a constitutional convention drafted a constitution which they adopted in November, and on Feb. 14, 1859, Oregon was admitted into the union with its present boundaries. Gold had been discovered in paying quantities at Jacksonville in southern Oregon in 1851 and in 1861 in eastern Oregon along the John Day and Powder rivers. Each of these discoveries resulted in a stampede which



FROM GRAY, "A HISTORY OF OREGON"
THE SETTLEMENT OF ASTORIA, OREGON, IN 1811, FOUNDED BY JOHN JACOB ASTOR AT THE HEAD OF THE COLUMBIA RIVER

settled a region which otherwise would have been settled very slowly. The increase of mining population in Oregon and Idaho encouraged agricultural development in that it provided markets.

Permanent settlements were made in all the important valleys of eastern Oregon in the 1860s. By 1870 the population of the state was 91,000. In the next 20 years it nearly doubled. This increase was due largely to the opening of railroad connections with the outside world. Two lines, one on each side of the Willamette river, to connect with a line in California, were begun in 1868, but progress was so slow that the connection was not made until 1887. Meanwhile a line had been built along the Columbia river to meet the transcontinental lines being built west through Idaho, and this junction was effected in 1883. Many local lines were also built.

Starting in the 1930s a vast program of public works was launched in the Columbia basin for the generation of electric power, improvement of navigation, irrigation and prevention of floods. Bonneville and Grand Coulee on the Columbia river (the latter in central Washington) were two large dams completed during this period.

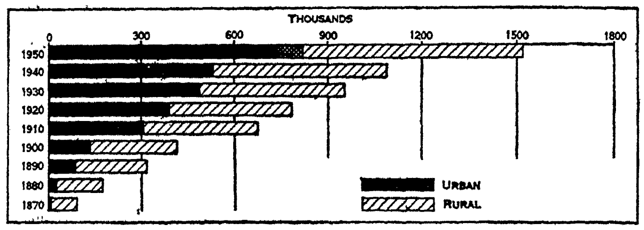
Politically the state at first was Democratic; in later years Republican. Of its 25 governors to 1950, 15 were Republican, 9 Democrat, 1 independent. Only six times had the state cast its vote for a Democratic candidate for president. It voted for F. D. Roosevelt four times and for T. E. Dewey in 1948.

Government.—Oregon is governed under its original constitution adopted in 1857, amended in a number of important respects. The legislative power is vested in a legislative assembly of two houses, but limited by direct action of the people through the initiative and referendum. The senate has a membership of 30 elected for four-year terms, and the house numbers 60 elected for two-year terms. The regular session begins in January of odd-numbered years. The governor has the single-item veto as well as the general veto. A two-thirds vote in each house is required to repass a bill over a veto.

Through a series of constitutional amendments and laws beginning in 1902, the people of Oregon adopted a number of reforms widely known as the "Oregon system." Its distinctive features were: (1) the initiative for legislative bills and constitutional amendments; (2) the referendum; (3) the direct primary; (4) a corrupt practices act; (5) presidential preference primary; (6) the recall; (7) a voters' pamphlet. Under the initiative proposed laws or amendments must be submitted to the voters at the next general election on the filing of petitions signed by 8% of the number voting for justice of the supreme court at the last general election. A total of 5% of the voters signing petitions procure a referendum on any law passed by the legislature, and the legislature itself may refer any law it has approved to the people for their approval. All elected public officials are subject to the recall, but it is rarely invoked. The voters' pamphlet (campaign textbook) contains the text of measures to be voted on and arguments for and against, also informational material inserted by candidates. The pamphlets are distributed to all registered voters.

The executive power in Oregon is vested in a governor elected for a four-year term. There is no lieutenant governor. The elected administrative officials are the secretary of state, treasurer, attorney general, superintendent of public instruction and labour commissioner, all elected for four-year terms. There are a number of boards and commissions, some ex officio such as the board of control and state land board, others appointive such as the board of forestry, board of health, board of higher education, parole board, library board, public employees' retirement board, highway commission, tax commission, industrial accident and unemployment compensation commissions, public welfare commission, civil service commission, fish and game commissions and liquor control commission. Appointive heads of departments include the adjutant general, director of agriculture, budget director, insurance commissioner, public utilities commissioner and corporation commissioner. In most instances the appointing power rests with the governor. The administration of justice is entrusted to a supreme court, circuit courts, district courts, county judges and justices of the peace. There are municipal courts in cities. The supreme court has seven members elected for six-year terms. Sessions of the court are held in Salem and Pendleton. The state is divided into 21 judicial districts for the circuit court, and some of the districts have several judges. In civil cases three-fourths of a jury may render a verdict. The county court is an administrative body consisting of the county judge and two commissioners. The county judge, except in certain counties, also handles probate and juvenile court matters.

Population.—The population of Oregon in 1850 was 13,294; in 1880 it was 174,768; in 1910, 672,765; in 1940, 1,089,684; and in 1950, 1,521,341. This last figure represented an increase of 39.6% over the population in 1940. The population per square mile in 1950 was 15.8, as compared with 11.3 in 1940, and with 50.7 for the U.S. in 1950.



BY COURTESY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF OREGON: 1870 TO 1950

The crosshatched part of the 1950 bar represents the population of the additional areas counted as urban under the new 1950 definition

Of the 1950 population, 732,247 or 48.1% lived in incorporated places of 2,500 or more, as compared with 48.8% in 1940, when these places constituted the urban area. The entire urban population, under a new definition set up for 1950 which included also the thickly settled suburban area, or "urban fringe," adjacent to the city of Portland, and two unincorporated places of 2,500 or more outside this fringe, amounted to 819,318, or 53.9% of the state total.

Area	Population			Per cent of increase	
	1950	1940	1930	1940–50	1930–40
The state	1,521,341	1,089,684	953,786	39.6	14.2
Urban	819,318*	531,675	489,746	54.1	8.6
Rural	702,023*	558,009	464,040	25.8	20.3
Per cent urban	53.9*	48.8	51.3	..	..
Principal cities:					
Portland	373,628	305,394	301,815	22.3	1.2
Salem	43,140	30,908	26,266	39.6	17.7
Eugene	35,879	20,838	18,901	72.2	10.2

*Final figures for 1950 based on *new* definition. *See* comment in text.

The number of occupied dwelling units (or households) in 1950 was approximately 480,000, as compared with 338,000 in 1940. The average population per household was 3.2, both in 1940 and in 1950.

The population of the state was distributed by colour and nativity in 1950 as follows: 92.9% native white, 5.5% foreign-born white and 1.6% nonwhite, mainly Indians. Of the foreign-born white, 22.5% were born in Canada, 9.5% in Germany and 8.3% in Sweden. There were 102.2 males per 100 females in the native white population and 117.2 in the foreign-born; 8.7% of the population was 65 years old or over; and 54.5% of the population 14 years old and over was in the labour force. Of the total number of employed males, 14.4% were engaged in agriculture, 9.8% in construction, 27.3% in manufacturing, 9.8% in transportation and 17.7% in wholesale and retail trade.

Finance.—The assessed valuation of taxable property was $1,607,876,262 in 1950 and $896,787,005 in 1940. Total receipts of the state treasury for the fiscal year 1949–50 were $288,392,748 and total disbursements $296,777,971. Cash balances in all funds on June 30, 1950, were $162,681,344. The principal fund is the state general fund which is derived chiefly from personal income and corporate excise taxes, inheritance taxes and profits of state liquor stores. No direct property tax for state purposes was levied after 1940. Total property taxes levied for 1950–51 for local units of government were $96,476,733.

Oregon initiated the tax on gasoline as a means of financing highway construction and maintenance.

Total bonded indebtedness of the state in 1950 was $29,427,820, of which the chief items were $21,000,000 for veterans' loan fund, $5,075,000 for veterans' World War I state aid and $2,237,500 for

highway bonds. Provisions were made for retirement of all bonds at maturity. County bonded debt in 1950 was $5,000,000 for roads. Bonded debt of school districts was $47,260,000; of cities $47,335,000. On June 30, 1950, there were 21 national banks with 86 branches and 52 state banks with 12 branches in Oregon. Aggregate deposits on Oct. 4, 1950, were $1,478,647,190.

Education.—Public schools of Oregon are operated by school districts. There is a state board of education with limited powers and a state department of education headed by an elective superintendent of public instruction. Total school enrolment in 1949–50 was 281,309 and in 1939–40, 205,928; high school enrolment 1949–50 was 69,020, in 1939–40, 63,057; parochial school enrolment in 1948–49 was 16,416, in 1939–40, 10,967. Total cost of public-school education in 1948–49 was $58,161,000 and in 1939–40, $18,126,538. In 1948–49 there were 10,568 teachers employed in public schools at an average salary of $3,130. Oregon Technical institute is maintained at Klamath Falls under the state board of education; in 1949–50 its enrolment was 708.

The state board of higher education operates seven institutions of higher learning: University of Oregon at Eugene; University of Oregon medical and dental school at Portland; Oregon State college, a land-grant college, at Corvallis; three colleges of education at Monmouth, Ashland and La Grande; and Vanport Extension centre under the extension division at Portland. Enrolment in the seven institutions in 1949–50 was 19,269 and in addition 16,716 were enrolled in extension classes. The state college operates an agricultural experiment station at Corvallis and nine branch stations over the state and conducts the agricultural extension service in co-operation with the federal department of agriculture. Besides the state institutions of higher learning there were 12 independent colleges and normal schools in Oregon in 1950.

Penal and Charitable Institutions.—In 1951 the state operated 11 penal and charitable institutions under the state board of control. Inmate population on June 30, 1950, was 4,375 in the two mental hospitals at Salem and Pendleton; 1,452 in the penitentiary at Salem; 1,242 in Fairview home for feeble-minded at Salem; 419 in three tuberculosis hospitals in Salem, The Dalles and Portland. Other institutions were schools for the deaf and blind and Hillcrest girls' training school at Salem, boys' training school at Woodburn.

Public welfare expenditures for old-age and general assistance, aid to dependent children and the blind for 1949–50 amounted to $25,687,637. Payments for unemployment compensation for that year were $25,893,895.

Agriculture and Livestock.—Agriculture is a major source of income in Oregon. Of the land area of 61,664,000 ac. in 1945 19,754,257 ac. or 32% were in farmland. The number of farms increased from 61,829 in 1940 to 63,125 in 1945. The average size of farms was 290.9 ac. in 1940 and 312.9 in 1945. The value of farmlands and buildings was $476,817,354 in 1940 and $697,775,183 in 1945. The value of implements and machinery was $44,607,932 in 1940 and $66,656,778 in 1945. The number of farm tenants decreased from 11,277 in 1940 to 6,823 in 1945.

Wheat, the chief grain crop, is produced mainly in the drier portion east of the Cascade mountains. In 1950 the wheat acreage was 940,000 and production was 24,215,000 bu.; average production for 1939–48 was 21,906,000 bu. Acreage and production of other important field crops in 1950 were as follows, with average production for 1939–48 in parentheses: oats 308,000 ac., 9,856,000 bu. (9,655,000 bu.); barley 415,000 ac., 14,525,000 bu. (8,774,000 bu.); potatoes 39,000 ac., 12,870,000 bu. (10,164,000 bu.); all hay 1,113,000 ac., 1,909,000 tons (1,942,000 tons).

Oregon is an important fruit-raising state and many of its valleys are noted for high quality fruits; *e.g.*, Rogue river for pears and Hood river for apples. Fruits, berries and nuts are grown extensively in the Willamette valley. Apple production was 2,788,000 bu. in 1950 (1939–48 average 2,783,000 bu.); pears 5,574,000 bu. in 1950 (1939–48 average 4,592,000 bu.). Cherry production was 19,700 tons in 1950 and prunes 20,700 tons.

Oregon produces a variety of specialty crops including hops, peppermint oil, vegetables, English walnuts, filberts, nursery stock and many seed crops.

Irrigation is employed extensively. In eastern Oregon it is necessary for crop production except where precipitation is sufficient for dry-land farming; it is also used in western Oregon to obtain maximum production for pasture and crops. In eastern Oregon irrigation districts, often in conjunction with the U.S. bureau of reclamation, manage the storage and distribution of water to lands; in western Oregon irrigating is usually an individual enterprise, water being drawn from wells or surface streams and distributed to lands through pipe and overhead sprinklers. Major irrigation developments are Owyhee, Deschutes, Umatilla, Klamath and Rogue river. The area under irrigation in 1950 was estimated at 1,130,000 ac., of which 465,812 ac. were in the 54 active irrigation districts on July 1, 1950.

The aggregate value of livestock on Oregon farms on Jan. 1, 1950, was $149,389,000, an increase of 50% from the average for 1939–48. Great numbers of beef cattle are raised on the farms and ranges of eastern Oregon while the Willamette valley and coast districts are devoted more to dairying. The number of all cattle and calves on Jan. 1, 1950, was 1,107,000, valued at $121,770,000. Of these, 383,000 were milch cows and heifers and heifer calves, valued at $36,240,000. Total milk production in 1949 was 1,305,000,000 lb. Numbers of sheep and lambs had declined steadily and stood at 689,000 valued at $12,212,000 on Jan. 1, 1950; numbers in 1930 were 2,530,000. Wool production decreased from 14,016,000 lb. in 1940 to 5,366,000 lb. in 1950. Horses and mules decreased from 301,000 in 1930 to 74,000 on Jan. 1, 1950, with a value of $2,836,000. Hogs numbered 166,000 in 1950 with a value of $4,233,000. Poultry raising is an important industry. On Jan. 1, 1950, there were 3,584,000 chickens valued at $5,627,000 and 370,000 turkeys valued at $2,405,000.

Mining.—Between 1851 and 1880 the mining of gold was a major occupation in Oregon and was responsible for the settlement of many localities. This continued with varying degrees of activity until World War II, when mining of precious metals ceased. Gold production was 93,372 troy ounces in 1939, valued at $3,268,000; in 1949 it was 16,226 oz. with a value of $567,910. Value of all mineral production in 1939 was $8,636,440 and in 1949 $22,479,000, of which metallic production amounted to only $676,000. Chief mineral products in 1949 were clay and clay products $1,196,177; sand and gravel $7,682,272; stone $6,479,164. In 1950 three portland cement plants were operating in the state; also one coal mine in Coos county, two gold lode mines and 40 gold dredges seasonally. Several plants were supplying lightweight aggregates: pumice, perlite and expanded shale (haydite).

Fisheries.—Fisheries production for 1949–50 amounted to 39,173,00 lb. valued at $7,389,000. Fish and shellfish are caught in coastal streams and the ocean and marketed fresh or canned. Principal fish are salmon, tuna, shad and bottomfish, the last a grouping of several species of ocean fish.

Forests and Lumbering.—Oregon contains the largest body of standing timber in the U.S., and its annual cut of lumber is the largest of all the states. The volume of standing timber in 1950 was 355,000,000,000 bd.ft. The area of timberland in the state was 29,755,000 ac. There were 13 national forests in Oregon, located principally in the mountain ranges, embracing 14,820,000 ac. with 157,000,000,000 bd.ft. of saw timber. Lands in state forests amounted to 687,400 ac. The amount of timber cut in 1949 was 6,874,953,000 bd.ft., and the plywood production was 709,149,000 sq.ft., ⅜-in. basis. Value of timber cut in 1949 was $309,000,000, green rough basis. The comparative figure for 1940 was $130,000,000.

The forests are largely of softwood. In western Oregon are some of the finest stands in the world of Douglas fir, western hemlock, spruce and western cedar. The chief commercial species east of the Cascades is ponderosa pine.

Oregon enacted advanced legislation for forest conservation and reforestation of cutover and burned-over lands. Many private owners of timberland became engaged in a "tree farms" program for continued cropping of lands in forests.

Manufactures.—Manufacturing showed rapid expansion in the state as indicated in comparative figures reported by the census bureau for 1947 and 1937, the figures for the latter year

in parentheses: number of establishments 3,075 (2,107); number of employees, average for year 105,591 (73,033); salaries and wages $317,827,000 ($94,162,000); value added by manufacture $675,017,000 ($169,057,000). The chief manufacturing industry is lumbering, with 1,390 establishments in 1947 which employed 51,550 persons, paid wages of $164,203,000 and gave added value of $363,561,000. Second was food and kindred products: 545 establishments with 17,761 employees, wages $46,063,000, value added by manufacture $107,767,000. Values added by manufacture in other important industries were: paper and allied products $34,653,000; printing and publishing $24,311,000; fabricated metal products $20,685,000; primary metal industries $19,782,000; furniture and fixtures $15,300,000. Canning and freezing of fruits, berries and vegetables are important.

Transportation and Commerce.—Total steam railway mileage of the state increased from 3,779 mi. in 1929 to 4,996 in 1939 and 5,054 in 1949. Electric railway mileage decreased from 364 mi. in 1929 to 105 in 1949. Main steam railway lines are those of the Southern Pacific, Union Pacific, Great Northern, Northern Pacific and Spokane, Portland and Seattle. The Southern Pacific operates a main line from Portland south across the state to California with numerous branch lines through western Oregon. The Union Pacific crosses the northeastern corner of the state to the Columbia river, which it follows to Portland. The Spokane, Portland and Seattle, jointly owned by the Great Northern and Northern Pacific, operates a line on the north bank of the Columbia river to Portland, thence on the south bank to Astoria and Seaside, as well as subsidiary lines in the Willamette valley and central Oregon. The Great Northern makes a connection from Bend through Klamath Falls to the Western Pacific in California. The state system of highways on Dec. 31, 1949, included 7,320 mi., of which 6,824 mi. were surfaced. There were 32,566 mi. of county roads, of which 16,889 were surfaced. In the fiscal year 1949–50 the state highway department (created in 1917) expended $34,974,459. Revenues were derived from fuels tax ($25,958,666 in 1949–50), motor vehicle registrations and drivers' licences ($9,709,880) and use fees from commercial vehicles ($5,545,387), also federal funds.

A deepwater channel in the Columbia and Willamette rivers makes Portland accessible for ocean-going vessels. Other principal ports are Astoria and Coos Bay. Tonnage figures on waterborne commerce at Portland for 1949 in domestic and foreign trade were, inbound 6,351,255 short tons, outbound 1,582,042 tons. Total cargo tonnage of merchandise exports for the Oregon customs district was 736,600 tons in 1949; imports 56,250 tons.

Air transportation in 1950 was provided by United Air Lines, Northwest Airlines, Western Air Lines, West Coast Airlines, Pan American World Airways, Southwestern Airways and Empire Air Lines.

OREGON CITY, a city of Oregon, U.S., on the east bank of the Willamette river, 12 mi. S. by E. of Portland; the county seat of Clackamas county. It is on federal highway 99E, and is served by the Southern Pacific and electric railways, and by motor coach lines. Pop. (1950) 7,682; it was 6,124 in 1940 and 5,761 in 1930. The river there makes a plunge of 40 ft. over a basalt ridge, and then flows between steep walls of solid rock 20 to 50 ft. high. The residential section, on the plateau above the cliff, is served by North America's only "perpendicular street" —an elevator which carries passengers up- and downtown. Abundant water power makes Oregon City a centre for paper and pulp, woollen fabrics and other commodities. John McLoughlin, a chief agent of the Hudson's Bay company, established a claim to the falls and city site and erected a mill and residence.

In 1840 Oregon City was platted, but McLoughlin's claim was disputed by a Methodist misson. And in 1850 congress awarded a great part of the claim for a university. This was rectified in 1862 with restoration of the land to McLoughlin's heirs by the Oregon legislature. In 1924 a commission-manager form of government was adopted.

OREGON GRAPE (*Mahonia aquifolium*), a North American evergreen shrub of the family of Berberidaceae, closely allied to the barberry (*q.v.*), and found from British Columbia to Oregon. It grows from three to ten feet high and bears large pinnate leaves composed of five to nine thick, spiny-toothed, somewhat hollylike leaflets, bright yellow flowers in erect racemes, followed by showy clusters of small blue berries. The plant is the floral emblem or state flower of Oregon, and is widely grown as an ornamental.

OREGON MYRTLE (*Umbellularia californica*), a North American tree of the laurel family (Lauraceae, *q.v.*), called also California laurel, native to Oregon and California. It occasionally attains a height of 90 ft. and a trunk diameter of 5 ft., but is usually much smaller. The tree features lance-shaped, fragrant evergreen leaves, greenish-yellow flowers, in small clusters, and a somewhat olivelike, dark purple fruit (drupe). The wood is one of the most valuable cabinet timbers of the Pacific states.

OREGON PINE: *see* Douglas Fir.

OREGON TEA TREE (*Ceanothus sanguineus*), a name given to a large shrub of the buckthorn family (Rhamnaceae), called also buckbrush, native from northern California to British Columbia and eastward to Montana. It grows about ten feet high and bears reddish branchlets, thin, smooth, ovate, toothed leaves, and compound clusters, two to four inches long, of small white flowers. As in the case of the New Jersey tea (*q.v.*), its leaves have been used as tea. (*See* Ceanothus.)

OREGON TRAIL: *see* Old Oregon Trail.

O'REILLY, JOHN BOYLE (1844–1890), Irish-American politician and journalist, was born near Drogheda, Ire., June 28, 1844, the son of a schoolmaster. After some years of newspaper experience, during which he became an ardent revolutionist and joined the Fenian organization known as the Irish Republican Brotherhood, he enlisted in 1863 in a British cavalry regiment with the purpose of winning over the troops to the revolutionary cause. At this period wholesale corruption of the army, in which there was a very large percentage of Irishmen, was a strong feature in the Fenian program, and O'Reilly was successful in disseminating disaffection in his regiment. In 1866 the extent of the sedition in the regiments in Ireland was discovered. O'Reilly was tried by court-martial and sentenced to be shot, but the sentence was commuted to 20 years' penal servitude. After confinement in various English prisons, he was transported in 1867 to Bunbury, Western Australia. In 1869 he escaped to the United States and settled in Boston, where he became editor of *The Pilot,* a

Roman Catholic newspaper. He subsequently organized the expedition which rescued all the Irish military political prisoners from the Western Australia convict establishments (1876). He was the author of several volumes of poetry, and of a novel of convict life, *Moondyne* (1879).

He died in Hull, Mass., on Aug. 10, 1890.

See J. J. Roche, *Life of John Boyle O'Reilly* (1891).

OREL (now ORYOL), a region of the Russian S.F.S.R., surrounded by the regions of Tula, Smolensk, Mogilev, Gomel, Chernigov, Sumy, Kursk, Voronezh and Ryazan. Area 25,669 sq.mi. Pop. (1939) 3,482,388. Orel forms part of the Black Earth area (central), which was created in 1928. The region consists mainly of dissected plateau, drained by the Oka and its tributaries, flowing into the Volga, and the Sosna. On the water partings between the streams, the Kurgans or artificial mounds, some containing burials and some being remains of earthworks, stand out sharply. In the Bolkhov and Dmitrov districts, the soil is podzol (*see* RUSSIA: *Soils and Their Influence*), but the rest of the region is covered with black earth. The forests have almost disappeared and a scarcity of wood and fuel exists. For climate, the difficulties of agriculture and social conditions *see* VORONEZH. Average January temperature 14.8° F., average July 67°.

The chief crops are rye, oats, potatoes, millet and hemp. Very little wheat or sunflower seed is grown. Cattle, sheep and pigs are bred; in pre-World War I times Orel was noted for horse breeding, but their numbers diminished greatly because of war requisitions and they were slow to recover. Livensk and Maloarchangelsk have, however, recovered their former position in regard to horse breeding. Factory industries include the making of chemical manure from the phosphorites of the region, iron mining and smelting in the Zinoviev district, near Dmitrovsk, and at Elets, flour milling, distilling, leather and chalk. Koustar (peasant) industries include the making of plows, rope, makhorka tobacco, carpets and, in Elets, lace. The region suffered much during the civil war 1917–20, and Elets changed hands several times. The chief towns are Orel and Elets.

In the 9th century a Slav tribe, the Vyatichis, was established on the Oka river and paid tribute to the Khazars. They recognized the rule of Rurik from 884 and were later absorbed in the principality of Chernigov. Their wealthy towns and villages were devastated by the Mongols in 1239–42 and the region was reduced to poverty. The Russians erected forts and established colonies in the 16th century. In 1610 Orel then known as the Ukrayna or Ukraine (*i.e.*, "border region") was the scene of civil warfare under the false Demetrius. From 1917 to 1920 it was again the scene of civil struggles.

Orel (now Oryol), the chief town of the above region, situated at the confluence of the Orlik with the Oka river, and at the junction of roads and railways linking it with Moscow, Bryansk, Kharkov and the east, in 53° N., 36° 8′ E. Pop. (1939) 110,567.

O'RELL, MAX, the *nom-de-plume* of PAUL BLOUET (1848–1903), French author and journalist, who was born in Brittany in 1848. He is chiefly remembered for his once famous book, *John Bull et son Île*. He died in Paris, on May 25, 1903.

ORELLANA, FRANCISCO DE (*c.* 1490–*c.* 1546), Spanish soldier and first discoverer of the Amazon, was born at Truxillo about 1490. He sailed for Peru in 1535, and in 1540–41 accompanied Pizarro's expedition from Quito to Napo in the capacity of lieutenant. Early in 1541 he was sent ahead of the main party to obtain provisions, but he deserted his charge, either from necessity or choice, and continued his journey down the Rio Napo to the valley of the Amazon, whose course he explored from its source in the Andes to the Atlantic; he reached the coast in Aug. 1541. He is reported to have encountered a tribe of female warriors, of whom he had been told by the Indians, and from whom the name of the river is derived. On his return to Spain he was granted the right to conquer the newly discovered lands, but an expedition, undertaken in 1544 for this purpose, met with little success. Orellana died, probably in Venezuela, about 1546.

See "The Voyage of Francisco de Orellana down the River of the Amazons," trans. C. R. Markham, from A. de Herrera's *Historia general de las Indias occidentales,* Hakluyt Society *Publications,* vol. xxiv (1859).

ORELLI, JOHANN CASPAR VON (1787–1849), Swiss classical scholar, was born at Zürich on Feb. 13, 1787. His cousin, JOHANN CONRAD ORELLI (1770–1826), was the author of several works in the department of later Greek literature. From 1807 to 1814 Orelli worked as preacher in the reformed community of Bergamo and published *Contributions to the History of Italian Poetry* (1810) and a biography (1812) of Vittorino da Feltre, his ideal of a teacher. In 1814 he became teacher of modern languages and history at the cantonal school at Chur (Coire); in 1819, professor of eloquence and hermeneutics at the Carolinum in Zürich, and in 1833 professor at the new university, the foundation of which was largely due to his efforts. He had already published (1814) an edition, with critical notes and commentary, of the *Antidosis* of Isocrates. The three works upon which his reputation rests are the following. (1) A complete edition of Cicero in seven volumes (1826–38). (2) The works of Horace (1837–38; 4th ed., 1886–92). (3) *Inscriptionum Latinarum Selectarum Collectio* (1828; revised edition by W. Henzen, 1856). His editions of Plato (1839–41, including the old scholia, in collaboration with A. W. Winckelmann) and Tacitus (1846–48, new ed. by various scholars, 1875–94) also deserve mention. Orelli died at Zürich on Jan. 6, 1849.

See *Life* by his younger brother Conrad in *Neujahrsblatt der Stadtbibliothek Zurich* (1851); J. Adert, *Essai sur la Vie et les Travaux de Johann Caspar Orelli* (Geneva, 1849); H. Schweizer-Sidler, *Gedächtnisrede auf Johann Caspar Orelli* (Zürich, 1874); C. Bursian, *Geschichte der klassischen Philologie in Deutschland* (1883).

ORENBURG (now CHKALOV), region of the Russian S.F.S.R. consisting of the former Orenburg and Orsk districts of the larger pre-1914 province of the same name. Area 22,085 sq.mi. Pop. (1939) 1,677,013. It is a narrow strip between Bashkiria on the north and Kazakstan on the south, widening out to the east and west. The province is hilly, except for the valleys of the Ural river and its tributaries, the Sakmara and the Or. It belongs to the region of perennial drought and dry and desert steppe. The soils are chestnut-brown clays and sands with salt efflorescences, on which crops can be raised successfully if drought is not too severe and if careful attention is paid to manuring and to the type of cultivation. Some fertile black earth occurs in the valleys. The average January temperature is 3.4° F., July 70.9° F., average rainfall 15.2 in. Coal and rich layers of rock salt are found near Iletsk, in the south of the province and phosphorite exists. The peasants are specially skilled in the preparation of leather, and the women knit the famous Orenburg goats' wool shawls.

The district lies on the border region between the territory of the Bashkirs and that of the Kirghiz; the Bashkirs were brought under Russian rule in 1557, and the fort of Ufa was built to protect them from Kirghiz raids. The frequent risings of the Bashkirs and the raids of the Kirghiz led the Russian government in the 18th century to erect a line of forts and blockhouses on the Ural and Sakmara rivers, which were afterward extended southwestward toward the Caspian and eastward toward Omsk, and Chkalov became the central point of these military lines.

ORENBURG (now CHKALOV), the chief town of the region of the same name in the Russian S.F.S.R., on the Ural river in 51° 46′ N., 55° 7′ E. Pop. (1939) 172,925. The opening of the Orenburg-Tashkent railway in 1905 greatly increased its importance, and it has an important railway workshop for this line. Its industries include the making of metal goods and bricks, sawmilling and brewing. Trading caravans from the central Asiatic republics bring carpets, silk, cotton, lambskin, wool and dried fruits to Orenburg to exchange against textiles, metal goods and other products of European Russia. Cattle, horses and sheep from the steppe lands are brought to its market, and animal products including frozen meat, hides, sheepskins, tallow and bristles are sent by rail to Samara and the west. Its population is mixed and includes Russians, Tatars, Kirghiz and Bashkirs, among others. In 1735 a fort was erected at the confluence of the Or and Ural rivers as an outpost of Russia against the Bashkirs and Kirghiz, and was called Orenburg. In 1740–43, the fortress was moved 120 mi.

down the Ural river to its present position and the former Orenburg was renamed Orsk. Heavy fighting occurred here after the 1917 revolution, and in that year its population was swollen to 140,588 by refugees. During the famine of 1920–21, the town suffered severely and the population dropped proportionately.

ORENDEL, a Middle High German poem, of no great literary merit, dating from the close of the 12th century. The story is associated with the town of Treves (Trier), where the poem was probably written. The introduction narrates the story of the Holy Coat, which, after many adventures, is swallowed by a whale. Orendel, son of King Eivel of Treves, who had embarked with 22 ships in order to woo the lovely Brida, the mistress of the Holy Sepulchre, is wrecked, and falls into the hands of the fisherman Eise, in whose service he catches the whale and recovers the Holy Coat. The poem exists in a single manuscript of the 15th century, and in one printed version dated 1512. It has been edited by F. H. von der Hagen (1844), L. Ettmüller (1858) and A. E. Berger (1888); there is a modern German translation by K. Simrock (1845).

See H. Harkensee, *Untersuchungen über das Spielmannsgedicht Orendel* (1879); F. Vogt, in the *Zeitschrift für deutsche Philologie,* vol. xxii (1890); K. Müllenhoff, in *Deutsche Altertumskunde,* vol. i, 2nd ed. (1890), pp. 32 *seq.;* R. Heinzel, *Über das Gedicht von König Orendel* (1892).

ORENSE, an inland province of northwestern Spain, formed in 1833 of districts previously included in Galicia, and bounded on the north by Pontevedra and Lugo, east by Leon and Zamora, south by Portugal, and west by Portugal and Pontevedra. Pop. (1950) 466,302; area 2,695 sq.mi. The province is almost everywhere mountainous. Its western half is traversed in a southwesterly direction by the river Miño; the Sil, a left-hand tributary of the Miño, waters the northeastern districts; and the Limia rises in the central mountains and flows west-southwest, reaching the sea at the Portuguese port of Viana do Castello. The railway from Monforte to Vigo runs through the province. There are iron foundries. The chief towns are Orense (*q.v.*), Allariz (1,819), Carballino (2,469), Viana del Bollo (980) and Nogueira de Ramuín (7,791). The province fell to insurgent troops early in the civil war of 1936–39.

ORENSE, an episcopal see and the capital of the Spanish province of Orense, on the left bank of the river Miño, and on the Tuy-Monforte railway. Pop. (1950) 55,574. The river is there crossed by one of the most remarkable bridges in Spain. It was built by Bishop Lorenzo in 1230, but has frequently been repaired. The image of El Santo Cristo in the Gothic cathedral is celebrated throughout Galicia. The warm springs known as Las Burgas attract many summer visitors; the waters were well known to the Romans, as their ancient names, Aquae Originis, Aquae Urentes or perhaps Aquae Salientes, clearly indicate. They named Orense Aurium, probably from the alluvial gold found in the Miño valley. Chocolate and leather are manufactured, and there are sawmills, flour mills and iron foundries.

OREODONT, vernacular name for any member of the extinct family Merycoidodontidae. The oreodonts were piglike in general appearance and structure, but the teeth were like those of ruminants. They were related to both pigs and ruminants, but only distantly. Extremely abundant and varied throughout most of the age of mammals (late Eocene through Pliocene) in North America, oreodonts have not been found on other continents. (G. G. Si.)

ORESTES, in Greek legend, son of Agamemnon and Clytaemnestra. According to the Homeric story he was absent from Mycenae when his father returned from the Trojan War and was murdered by Aegisthus and Clytaemnestra. Eight years later he returned from Athens and revenged his father's death by slaying his mother and her paramour (*Odyssey,* iii. 306; xi. 542). For later forms of the legend of his return, *see* ELECTRA.

In post-Homeric writers, Orestes, after the deed, is pursued by the Erinyes (*q.v.*). He takes refuge in the temple at Delphi. Apollo sends him to Athens to plead his cause before the Areopagus. The Erinyes demand their victim; he pleads the orders of Apollo; the votes of the judges are equally divided, and Athena gives her casting vote for acquittal. The Erinyes are propitiated by a new ritual, in which they are worshipped as Eumenides (the Kindly), and Orestes dedicates an altar to Athena Areia. According to Euripides, some of the Erinyes were not satisfied, so Orestes was ordered by Apollo to go to Tauris, carry off the statue of Artemis which had fallen from heaven, and bring it to Athens. He repairs to Tauris with Pylades, the son of Strophius and the intimate friend of Orestes, and the pair are at once imprisoned by the people, among whom the custom is to sacrifice all strangers to Artemis. The priestess of Artemis, whose duty it is to perform the sacrifice, is his sister Iphigeneia (*q.v.*). A recognition is brought about, and all three escape together, carrying with them the image of Artemis. After his return to Greece, Orestes took possession of his father's kingdom of Mycenae, to which were added Argos and Laconia. To gain possession of Hermione, whom Neoptolemus had married, he murdered the latter at Delphi. He is said to have died of the bite of a snake. The development of the legend is the result (*a*) of the post-Homeric horror of bloodshed (Erinyes; to Homer, Orestes does nothing which is not entirely admirable); (*b*) of the growing interest in cases of conscience (conflict of the duty of revenge and the sacredness of his mother's person); (*c*) of the development of modern ideas of ethics and jurisprudence (the Areopagus consider motive and mitigating circumstances, instead of merely regarding the act); (*d*) of the replacement of blood-feud by state intervention and formal trial.

See Jebb, introduction to Sophocles, *Electra;* Höfer in Roschers *Lexikon,* art. "Orestes." (H. J. R.)

ORFE or GOLDEN ORFE, a variety, originating in Germany, of the ide (*Idus idus*), one of the Cyprinidae and allied fairly closely to the roach (*q.v.*).

ORFILA, MATHIEU JOSEPH BONAVENTURE (1787–1853), French toxicologist and chemist, was by birth a Spaniard, having been born at Mahon in Minorca on April 24, 1787. After studying medicine at the universities of Valencia and Barcelona, he settled in Paris to study under the chemist L. N. Vauquelin. In 1811 he graduated and immediately became a private lecturer on chemistry in the French capital. In 1819 he was appointed professor of medical jurisprudence, and four years later he succeeded Vauquelin as professor of chemistry in the faculty of medicine at Paris. In 1830 he was nominated dean of that faculty. He died in Paris on March 12, 1853. Orfila's fame rests on his *Traité des poisons,* or *Toxicologie générale* (1813).

ORFORD, ROBERT WALPOLE, 1st EARL OF (1676–1745), generally known as SIR ROBERT WALPOLE, prime minister of England from 1721 to 1742, third son of Robert Walpole, M.P., of Houghton in Norfolk, was born at Houghton on Aug. 26, 1676. He was an Eton colleger from 1690 to 1695 and was admitted at King's college, Cambridge, as scholar on April 22, 1696. At this time he was destined, as a younger son, for the church, but the death of two elder brothers made him heir to an estate producing about £2,000 a year, whereupon he resigned his scholarship and was withdrawn from the university.

Walpole sat in parliament at first for the family borough of Castle Rising (1701) and then for King's Lynn, which he represented until he was raised to the peerage. In June 1705 he was appointed one of the council to Prince George of Denmark, the inactive husband of Queen Anne, and then lord high admiral of England. On Feb. 25, 1708, he succeeded Henry St. John as secretary at war, and was thus brought into immediate contact with the duke of Marlborough and the queen. With this post he held for a short time (1710) the treasurership of the navy, and was admitted to the inmost councils of the ministry. He could not dissuade Godolphin from the impeachment of Henry Sacheverell, and when the committee was appointed in Dec. 1709 to draw up the impeachment Walpole was nominated one of the managers for the house of commons. Walpole shared in the general wreck of the Whig party, and in spite of the flattery, followed by the threats, of Sir Edward Harley he took his place with his friends in opposition. Both in debate and in the pamphlet press he vindicated Godolphin from the charge of peculation, and in revenge for his zeal his political opponents brought against him an accusation of personal corruption. On these charges he was in 1712 expelled from the house and spent a short time in the tower.

His prison cell became the rendezvous of the Whigs, while his praises were sung in popular ballads. In the last parliament of Queen Anne he defended Sir Richard Steele against the attacks of the Tories.

After the accession of George, the Whigs for nearly half a century retained the control of English politics. Walpole, who had supported the Hanoverian succession, obtained the lucrative post of paymaster-general of the forces in the administration which was formed under the nominal rule of Lord Halifax, but of which James Stanhope and Townshend were the guiding spirits. Walpole was chairman of the committee appointed to inquire into the acts of the late ministry, and especially into the Peace of Utrecht, with a view to the impeachment of Harley and St. John. Halifax died on May 19, 1715, and after a short interval Walpole became first lord of the treasury and chancellor of the exchequer (Oct. 11, 1715). Jealousies, however, prevailed among the Whigs, and the German favourites of the new monarch quickly showed their discontent with the heads of the ministry. Townshend was forced to resign his secretaryship of state for the viceroyalty of Ireland, but he never crossed the sea to Dublin, and the support which Sunderland and Stanhope, the new advisers of the king, received from him and from Walpole was so grudging that Townshend was dismissed from the lord-lieutenancy (April 9, 1717), and Walpole on the next morning withdrew from the ministry. They plunged into opposition with unflagging energy, and in resisting the measure by which it was proposed to limit the royal prerogative in the creation of peerages (March–December 1718) Walpole exerted all his powers. This display of ability brought about a partial reconciliation of the two sections of the Whigs. To Townshend was given the presidency of the council, and Walpole reassumed the paymastership of the forces (1720).

On the financial crash which followed the failure of the South Sea scheme, Walpole was regarded by the general public as the indispensable man. Stanhope and James Craggs, the two secretaries of state, died, John Aislabie, the chancellor of the exchequer, was committed to the tower, and Sunderland, though acquitted of corruption, was compelled to resign. Walpole, at first lord of the treasury and chancellor of the exchequer (April 1721), became with Townshend responsible for the government (though for some years they had to contend with the influence of Carteret), the danger arising from the panic in South Sea stock was averted by its amalgamation with Bank and East India stock, and during the rest of the reign of George I they remained at the head of the ministry. The hopes of the Jacobites, which revived with these financial troubles, were disappointed. Atterbury, their boldest leader, was exiled in 1723; Bolingbroke sued for pardon and was permitted to return to his own country. Peace was assured by a treaty between England, Prussia and France concluded at Hanover in 1725.

In 1727 George I died, but the confidence which the old king had reposed in Walpole was renewed by his successor, after a brief period of coldness, and in Queen Caroline the Whig minister found a faithful and lifelong friend. For three years he shared power with Townshend, but quarrelled with him in 1730, and Townshend retired into private life. Walpole's administration was based on two principles, sound finance at home and freedom from the intrigues and wars which raged abroad. On the continent congresses and treaties were matters of annual arrangement, and England enjoyed many years of peace. Walpole's influence received a serious blow in 1733. The enormous frauds on the excise duties forced themselves on his attention, and he proposed to check smuggling and avoid fraud by levying the full tax on tobacco and wine when they were removed from the warehouses for sale. His proposals met with violent opposition and had to be dropped. Several of his most active antagonists were dismissed from office or deprived of their regiments, but their spirits remained unquenched, as the incessant attacks in the *Craftsman* showed, and when Walpole met a new house of commons in 1734 his supporters were far less numerous. The Gin Act of 1736 led to disorders in the suburbs of London; and the imprisonment of two notorious smugglers in the Tolbooth at Edinburgh resulted in the Porteous riots described in the *Heart of Midlothian*. These events weakened Walpole's influence in the country, but his parliamentary supremacy remained unimpaired, and was illustrated in 1737 by his defeat of Sir John Barnard's plan for the reduction of the interest on the national debt, and by his passing of the Playhouse act, for the regulation of the London theatres.

That year, however, heralded his fall from power. His constant friend Queen Caroline died on Nov. 20, 1737, and Frederick, prince of Wales, whose request for an increase in his official allowance had been refused, became his active opponent. The prince controlled many boroughs within the duchy of Cornwall, and he attracted Pitt, the Grenvilles and others to his cause. The leading orators of England thundered against Walpole in the house of commons, and the press resounded with the taunts of the poets and pamphleteers, illustrious and obscure, who found abundant food for their invectives in the troubles with Spain over its exclusive pretensions to the continent of America and its claim to the right of searching English vessels. Walpole long resisted the pressure of the opposition for war, but at the close of 1739, as the king would not allow him to resign, he was forced into hostility with Spain. The Tory minority known as "the patriots" had seceded from parliament in March 1739, but at the commencement of the new session, in Nov. 1739, they returned to their places with redoubled energies. The successes of the troops brought little strength to Walpole's declining popularity, and in the new house of commons of 1741 political parties were almost evenly balanced. Their strength was tried immediately on the opening of parliament. Walpole was defeated. On Feb. 9, 1742 he was created earl of Orford, and two days later he ceased to be prime minister. A committee of inquiry into the conduct of his ministry for the previous ten years was ultimately granted, but its deliberations came to nothing. Walpole died at Arlington street, London, on March 18, 1745, and was buried at Houghton on March 25. With the permanent places, valued at £15,000 per annum, which he had secured for his family, and with his accumulations in office, he had rebuilt the mansion at great expense, and formed a gallery of pictures within its walls at a cost of £40,000, but the collection was sold by his grandson for a much larger sum in 1779 to the empress of Russia.

Walpole was twice married—in 1700 to Catherine Shorter (d. 1737) and in March 1738 to Maria Skerret.

Sir Robert Walpole's life has been written by Archdeacon William Coxe in 3 vol. (1798 and 1800), A. C. Ewald (1878) and John Viscount Morley (1889). *See* also Edward Jenks, *Walpole, a Study in Politics* (1894); *English Hist. Rev.* xv, 251, 479, 665, xvi, 67, 308, 439 (his foreign policy, by Basil Williams); Walter Sichel, *Bolingbroke*, 2 vol. (1901–02); the histories, letters and reminiscences by his son, Horace Walpole; and the other lives of the chief political personages of the period.

ORFORD, a small town on the River Alde, Suffolk, England, 20 mi. E.N.E. of Ipswich by road. Pop. (1931) 706. In the 12th century a thriving port, it had declined by the 16th century owing to the increase of the shingle spit known as Orford Ness which had pushed the mouth of the river farther down the coast. Of Orford castle the Norman keep remains, built of flint and Caen stone.

ORGAN. In music, organ is the name given to the familiar wind instrument played from keyboards (from Gr. ὄργανον; Lat. *organum,* instrument). It may be defined as a musical instrument gaining sound from pipes, these pipes being set on wind chests supplied with air under constant pressure. The flow of air to the pipes is controlled by intermediary mechanisms from one or more keyboards.

The name implies pipes; thus the designation "pipe organ" is redundant, as would be the term "string violin." A reed organ is more properly called a harmonium. Electronic devices devoid of pipes and reeds do not qualify for the name.

Early History: to 1500.—Music has been called the youngest of the arts, but among devices for the expression of music the organ is one of the oldest, and it was the first of the keyboard instruments. It is mentioned in the Old Testament, but the Greek word in Genesis translated "organ" is used in the same general sense that we use the term "instrument." Ancient fable ascribes the invention of the organ to Pan, the sylvan god, and relates that it was made from reeds that grew by the river. Considering the organ

superior to the lyre of Apollo, Pan challenged Apollo to a trial of skill, which Midas, the umpire, decided in favour of Pan's pipes.

In principle of musical speech, the beginnings of the organ may be seen in primitive flutes, fashioned from reeds or hollow sticks. These were grouped together into a syrinx, or pan pipe, a collection of hollow tubes of various lengths, bound side by side, raft fashion, and blown from the top. Some time later came the discovery that tone could be produced by blowing from the base of a tube and by deflecting the flow of air out of a slot cut in the side of the tube just above a partial obstruction. Possibly the next phase in the development of the organ resembled the modern bagpipes, when some inventive genius assisted human lung power by devising a wind reservoir out of a skin, leading to a handful of pipes, all of them stopped by the fingers except the one intended to speak.

This led to the first organ of which there is an actual record. Ctesibius, a Greek engineer of the 3rd century B.C., living in Alexandria, is credited with the evolution of the *hydraulis*, an instrument with the essential characteristics of the modern organs. It had a set of pipes, each of a different pitch and controlled in their speech by keys or levers, which admitted or shut off the wind as desired. The *hydraulis* gained its descriptive name from the method by which a supply of wind was provided. A reservoir of air under the necessary constant pressure was obtained by the immersion in water of a large cup or bell, on the principle of a diving bell, within a large container. The water compressed the air upward within the bell, and as the air was drawn off by the speech of the pipes it was replenished by bellows, connected to the bell. The blowing arrangement was ingenious in its simplicity for, if the bell was kept full so that a surplus of air constantly escaped from the bottom, the pulsation of air from the bellows was evened out by the constant weight and upward thrust of the water.

Hero in his *Pneumatica* (*c.* 3rd century B.C.) and Vitruvius in his *De Architectura* (*c.* 14 B.C.) describe the workings of this instrument. A clay model of a *hydraulis* was discovered in 1885 in the ruins of Carthage, and portions of an actual instrument were found in 1931 in Aquincum, near Budapest. Pictorial representations and writings of those centuries indicate that the *hydraulis* played a large part in the life of the period. Cicero relates that it was used at banquets and speaks of its sound as being as delectable to the ear as the most delicious fish to the palate. Other writings indicate that the *hydraulis* was used in the arena to accompany fights and circus performances. A notable performer on this early organ was the Roman emperor Nero (37–68 A.D.), and it is related that on an occasion of particular danger, from an insurrection of the Gauls under Vindex, Nero summoned his political advisers to a meeting, but after a brief conference spent most of the day showing them a new type of *hydraulis*.

FIG. 1.—HYDRAULUS BY AUDSLEY

Over the next few centuries the *hydraulis* evolved into the pneumatic organ, an instrument in which bellows supplanted the hydraulic mechanism as the source of wind supply. The first representation of such an organ dates from the 4th century A.D., on an obelisk at Constantinople, erected by the emperor Theodosius (died 395 A.D.). An earlier passage, even, in Pollux' *Onomasticon* from about the year 120 refers to "brazen pipes blown from below . . . by bellows." Descriptive references to the organ occur in an epigram by Julian the Apostate (331–363) and in the writings of St. Augustine (354–430). References to the organ occur frequently during the next few centuries, and the event of the year 757 for many writers was the arrival in Compiègne of an organ, a gift to King Pippin from the Byzantine emperor Constantine Copronymus. Around 950, a giant organ was constructed in England for the Old church in Winchester. It is vividly described by the monk Wulstan: "Twice six bellows are ranged in a row, and fourteen lie below . . . worked by seventy [seven?] strong men . . . the music of the pipes is heard throughout the town, and the flying fame thereof is gone out over the whole country. . . ."

FIG. 2.—ORGAN OF THE 11TH CENTURY

It would be interesting to know just what music was played on such instruments, but no manuscripts of organ music appear to have survived from these early centuries. No doubt music played on the rather sketchy keyboards was purely vocal in character and probably of just one melodic line, though the presence of two players in the illustration of the Utrecht Psalter of about 800 prompts the speculation that the melody was occasionally embellished with a second part.

Around 1100 the cathedral of Magdeburg acquired a notable organ, and in 1360 a large instrument was built by the priest Nikolaus Faber for the Halberstadt cathedral. Michael Praetorius notes that it had three keyboards and pedals, and it was the first organ to have a complete scale of semitones. Most of the organs to that time had been constructed by priests or monks, but one Albert van Os, who lived during the 12th century, has the distinction of being the first professional organ builder on record.

The Organ from 1500.—By 1500 organs had evolved in size and in refinement of tone. Principles of voicing and ensemble became generally understood. Certain reeds, flutes and other solo stops were added, expanding the tonal spectrum of the organ, and these new timbres were developed into complete tonal families, grouped on different manuals. The pedal organ was gradually evolved, its compass was extended, and its musical possibilities began to be realized. The mechanism of keyboards and pedals and of stop control became more readily workable. Progress to this point is summarized in Arnolt Schlick's *Spiegel der Orgelmacher und Organisten* (1511). At the same time smaller instruments known as *Positivs* and *Portativs* came into general use. They were instruments of varying degrees of sonority; the *Positivs* were

made small enough to be moved as occasion required, and the *Portativs* were occasionally used, as the accompanying illustrations show, in processions. Both types played a large part in music of the home, and much keyboard music of this period is interchangeable between the harpsichord and these small organs. Writing in 1676, Thomas Mace of Trinity college, Cambridge, describes and illustrates a small "table organ" that he built himself for his home. It included seven stops: diapason, principal, 12th, 15th, and "two-and-twentieth," regal and a "hooboy stop."

The expanding skill of the organ builder was matched by the growing imagination of the composer. From the 14th century on, a new style of writing developed at a great pace, exploiting the possibilities of the organ, and it was on organ manuals that keyboard music graduated from the imitatively vocal to the purely instrumental. The Reformation lent enormous impetus to organ composition, for the inspired and compelling chorales provided a musical treasure which composers later elaborated into countless chorale preludes and fantasies. Forms of composition took shape, the toccata, the various types of fugal writing; and the flowering of musical composition that took place over a period of almost four centuries centred largely around the organ. Not only was the organ an expressive medium, but for musicians of those days it was also the grandiose in music. Since most composers were also organists, they understood the nature of the instrument and set down some of their finest musical thoughts for the organ.

FIG. 3.—MEDIAEVAL PORTATIVE

The progress of these centuries was described in its instrumental aspect by Praetorius in his *Syntagma musicum* of 1618; the musical side was typified by the towering organ compositions of Johann Sebastian Bach (1685–1750). After 1750 the position of the organ in musical activity began to be challenged by the developing orchestra and by the newly invented pianoforte. The trend of musical composition was away from contrapuntal writing and toward a percussive and chordal type of texture not suited to organ performance. Though some organ builders valued and preserved the classic traditions of the instrument, others attempted innovations of questionable merit. Wind pressures were raised in order to obtain greater volume of sound from pipes with the unfortunate result that mixture and mutation stops, which become shrill on high wind pressure, were gradually omitted in organ specifications. A variety of soloistic stops designed to imitate orchestral instruments were substituted for stops of the basic ensemble. In quest of "expression" it became the habit to enclose practically all of the pipes in swell boxes, with shutters which could blanket the tone in varying degree. With some notable exceptions, organ builders of the 19th century pursued the goal of a "romantic expressiveness," but frequently succeeded only in producing instruments of thickened sonorities, embellished with imitative orchestral stops, yet lacking in authentic organ ensemble.

During these years players tended to forget their unequalled heritage of music and spent much effort in attempting to imitate the orchestra and to play the orchestral repertoire on the organ. In the 20th century, the motion picture theatre organ made its entrance and its exit. Perhaps this sort of instrument, at its best only with the poorer types of music, may represent the culmination of this less fortunate phase of organ building, which bears little relation to the centuries-old tradition of the instrument.

On the other hand, the 20th century also saw a reawakening on the part of musicians and organ builders to the fundamentals of their art. In many modern organs practices of classic design and voicing became re-established, and this progressive trend restored the musical prestige of the instrument. Principles of ensemble—the blending of stops of different pitches into a homogeneous sonority—were carried out with increasing success. Low wind pressures were again recognized as essential, and many progressive organ builders left the mouths of most pipes unnicked, thus preserving a slight and agreeable accent in the speech. Moreover, it was realized anew that an organ ideally must be placed completely in the open, for undue enclosure will restrain and damage the tone. A pipe in the open is worth two in a box, for a soft sound, unenclosed, has presence and beauty, but a louder tone blanketed in a swell box, or even in the recess of an organ chamber, loses presence and is by no means a satisfactory substitute. Through modern ingenuity a good organ touch has the responsive character of the keys of a grand piano, with the particular difference that the speech of a pipe is unaffected by the degree of force with which a key is depressed. A more readily playable pedal board of radiating and concave design came into general use, replacing the previous flat and parallel pattern of keys.

The organ remains an instrument best suited to the horizontal rather than the vertical type of music—that is, to flowing contrapuntal lines rather than chordal structures—and an instrument of individual colours and a variety of ensembles not imitative of any of its musical relatives, but of a musically architectural character strictly its own. This return to the authentic tonal texture of the organ was paralleled by a new awareness of the instrument on the part of contemporary composers, and it is notable that the best of modern composition is closely allied to classic models, though harmony and idiom may be modern.

GENERAL DESCRIPTION

The sounds of an organ are produced by pipes of various lengths and shapes, set into musical speech by the flow of air under pressure. The sounding of these pipes is determined by the use of the keys, some of which are played by the hands, some by the feet. In appearance, the keys of an organ resemble those of a piano, but whereas a piano has one keyboard an organ may have several, each governing a division of pipes, in addition to a keyboard of pedals, played by the feet. The criterion of musical excellence inevitably resides in the voicing of the pipes, rather than in the size of the organ, and an instrument even of two manuals, with pedals, provides an adequate medium for by far the greater part of the organ repertoire, though instruments of three and four manuals offer advantages, and organs of as many as seven manuals have been built.

FIG. 4.—POSITIVE ORGAN OF THE 16TH CENTURY

Stops.—Organ pipes differ in two essentials from other wind instruments. A flute player, for example, obtains different notes by altering with his fingers the speaking length of his instrument and by blowing at different pressures. An organ pipe speaks one

note only and is voiced for an unvarying wind pressure. Even were it mechanically possible to alter the effective speaking length at will, and to vary the pressure of the wind supply, no musical advantage would be gained, for it would be impossible to play more than one note at a time.

An organ stop, set, register or rank, of pipes necessarily comprises one pipe (or more: see *Mixtures,* below) for each note of the keyboard. Each stop is a member of a section or division, controlled from one of the keyboards, and each manual division is in turn a part of the complete organ. To an organ builder a stop implies a set of pipes, though the same name is also given to the knob or tablet at the console which actuates the valve or slider, admitting or shutting off wind to the rank of pipes. Each stop has a separate knob or tablet, just as each note has a separate key, and unless one or more of the stops be drawn no sound will result when the keys are played. The pipes of a given stop all produce sounds of similar quantity, but naturally of different pitches. No two stops are exactly alike in musical timbre; on the contrary, they are designed to differ. Some have a thin, some a full quality of tone, and, moreover, some stops are of high pitch, some of low.

Divisions, Compass.—From the grouping of pipes into a stop, we pass next to the grouping of several stops into a section or division. Each of these "organs" is played from its own keyboard or manual and has its own characteristic timbre and utility. Briefly, these divisions are: The great organ, the positive or choir organ, the swell organ, the solo, orchestral, or bombarde organ, and the echo or antiphonal organ. Moreover, on all but the smallest instruments, there is a pedal organ. The assignment on different manuals of these various divisions varies among builders and among different countries; but certain basic principles have become established. A one-manual organ will have the character of the great. A two-manual is best designed as a great and positive, or choir, though a two-manual will often be made up of a great and swell. A three-manual will almost invariably consist of a great, positive or choir, and swell, while the remaining divisions will be controlled from a fourth or from additional manuals.

The usual compass of organ manuals is 61 notes, five octaves, from C in the bass to C'''' in the treble. The customary pedal compass is 32 notes, just over $2\frac{1}{2}$ octaves, from CC in the bass (lowest C on the pianoforte) to the G above middle C. Thus a manual stop ordinarily comprises 61 pipes and a pedal stop 32 pipes, offering between the pedals and manuals a tonal compass of six octaves. However, the total compass of the organ is often larger by three or more octaves than the six octaves mentioned, for in addition to the normal 8-ft. stops (see *Pitches of Stops* below) there may be others speaking one or two octaves higher or lower than implied by the controlling note on the keyboard. Thus a 32-ft. pedal stop carries down the pitch an octave lower, low C having a frequency of 16 vibrations a second, while a 2-ft. manual stop will extend the upward pitch two octaves higher, giving high C a frequency of more than 8,000 vibrations a second.

Pipes.—Organ pipes fall chiefly into the two categories of flues and reeds. The flue pipe in principle is similar to a tin whistle, except that a flue pipe is designed to sound one note only. In reed pipes, the wind vibrates a curved brass tongue held over the cut and flattened side of a brass tube called a shallot, so that the oscillations of the tongue cause the speech of the pipe. Associated with the reed is a cylindrical cone or pipe which acts as a resonator, giving security of pitch and adding quality to the tone. Such an organ stop is known as a beating reed and differs considerably in sound from the free reed employed without a resonator in the harmonium.

The pitch of a flue pipe is set by its length and, generally speaking, the width of the pipe determines the volume and quality of the tone, a wider diameter giving a fuller tone and a narrower diameter producing a keener sound. This relation of width to length is referred to as the scale of the pipe. On the other hand, the pitch of a reed pipe depends on the length of tongue set into vibration and is also affected by the thickness and tension of the tongue and the length, shape and scale of the resonator.

Flue pipes may be open, with the top of the pipe open to the air; or they may be closed or stopped with a stopper or cap covering the pipe at the top. The diapasons and principals are all open pipes; gedeckts and bourdons are stopped. A stopped pipe will sound a note an octave lower than an open pipe of the same length; and the even-numbered harmonics of the tone become minimized, giving a light and rather transparent quality to the sound.

Another type of flue pipe is made of double length, open at the top, pierced about midway with a small hole. Known as harmonic pipes and having a very bright tone, these give a sound an octave higher than open pipes of the same length.

Stops of the same name vary considerably in character and strength among different organs and in work of different builders. Names of organ stops, therefore, denote a general character rather than a specific quality and volume of sound. In the case of stops bearing the names of orchestral instruments the resemblance is only approximate.

Flue Stops.—Flue stops fall into three general categories: flutes, principals and viols. Flutes themselves divide into open and closed pipes. There are the half-length and stopped pipes (gedeckts, bourdons—also occasionally called stopped diapasons); the normal length and open (melodia, claribel, concert flutes) or double length (the harmonic flute).

Another class of flutes (the Koppel flute, Ger. *Rohrflöte,* Fr.

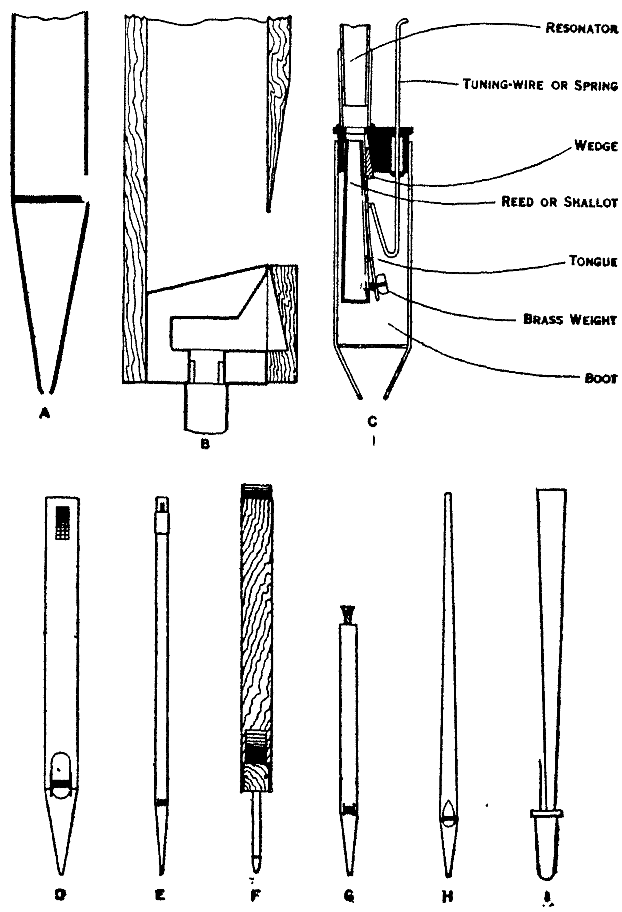

FIG. 5.—VARIOUS TYPES OF ORGAN PIPES

(A) Section of metal flue pipe; (B) section of wooden flue pipe; (C) section of reed pipe (trumpet) and its component parts; (D) open diapason; (E) Viola da gamba; (F) clarabella, or *Hohlflöte;* (G) Gedeckt; (H) Gemshorn or *Spitzflöte;* (I) trumpet or cornopean (reed). (Not to scale)

flûte à cheminée) is given a high harmonic development by being half stopped, with a small chimney of some form incorporated into the stopper.

Principals (Eng. diapason or Fr. *montre*) have the sound typically associated with the organ and are open pipes of medium scale. The principal-type stops of different pitches which furnish the ensemble of the organ are identified merely by their pitch;

octave, 12th, 15th, etc. Mixture stops are usually of principal character.

Viols, or string-toned stops such as the salicional, gamba, dulciana, etc., are made of pipes similar to the principals except that the scale is much reduced (*i.e.,* they are of smaller diameter in relation to length), and they are usually somewhat lighter in construction.

A tempered or muted tone, in various degrees of compromise, may be obtained by making the pipe in the shape of a long inverted cone. Thus the *Spitzflöte* and the gemshorn present a mixture of the species and have certain useful tonal characteristics.

Reed Stops.—Reed stops, which in all organs are far outnumbered by the flues, fall into three general divisions.

First there are the natural organ reeds, nonimitative in character, which have descended from the classic period of organ building. The krummhorn (or cromorne), regal, schalmei, and rankett are in this class. They have an authentic organ sonority, appropriate to organ music and are invaluable as solo stops or in ensemble. Resonators of these reeds are often made of fractional length, being half, a quarter or even one-sixteenth of the length implied by the note sounded.

Next are the reeds of the trumpet family (trumpet, trompette, trombone, clarion, cornopean, etc.) often known as chorus reeds. If not voiced too broadly, they serve a useful function in the chorus or ensemble, particularly on the pedals, and they are distinctive as solo stops.

The third group of reeds comprises the modern and frankly imitative stops—such as the clarinet (which is not unlike the older krummhorn), the oboe, orchestral oboe, the bassoon, English horn and French horn. Many of the imitative reeds require considerably higher wind pressures than the authentic organ reeds and flues.

Tuning.—Flue pipes are tuned by lengthening or shortening the effective speaking length, and this is accomplished by various methods according to the type of pipe in question. Some are tuned by moving up or down a metal slide or extension which fits over the top of the pipe. Others, particularly the smaller "upperwork" pipes, have to be coned in (closed) or expanded slightly at the top, according to whether it is desired to flatten or sharpen the pitch. Wooden pipes of some types are tuned by pressing in or pulling out a metal shade affixed in or near the top of the pipe. In the case of stopped pipes the caps or stoppers afford a ready means of altering the pitch.

Reeds are tuned by altering the position of a tuning wire or spring, which can be made to increase or diminish the length of reed allowed to vibrate. The length of the resonator must also be brought into sympathetic adjustment.

Pitches of Stops.—Organ pipes that speak at the pitch implied by the particular manual key played are called 8-ft. or unison stops, because an open pipe sounding the lowest note of the keyboard (that is, CC) is about 8 ft. in length. Gedeckts and reeds of half this length and harmonic pipes of double length, sounding the indicated pitch, are still referred to as 8-ft. stops.

On the manuals, then, a 16-ft. stop will sound notes one octave below normal pitch. Of stops sounding higher than 8-ft. pitch, 4-ft. stops give the octave, $2\frac{2}{3}$-ft. stops the 12th, 2-ft. stops the superoctave or 15th, $1\frac{3}{5}$-ft. stops the tierce or 17th, $1\frac{1}{3}$-ft. stops the larigot or nineteenth, 1-ft. stops the 22nd and so—in theory at least—ad infinitum, according to the natural law known as the harmonic series. Practical considerations, however, set arbitrary limits, and in this case they rule: (1) ranks above the 15th are too small and acute to be carried through the whole compass of the keyboard in an unbroken form; (2) no rank more dissonant than a minor seventh—or at most a major third—is tolerable in the tonal economy of the organ; (3) for most ordinary purposes, ranks sounding octaves, thirds and fifths sufficiently represent the harmonic series. As a matter of practice, all stops above the 15th form a part of what are called the mixtures, and except for special purposes are employed collectively as upper work. Manual stops of 16-ft., 8-ft. and 4-ft. pitches are termed foundation work (Fr. *fonds*). The 12th and 15th are usually independent ranks but are sometimes part of the mixtures. Thus foundation work and upper work complement each other into a complete tonal texture or ensemble.

Mixtures.—The mixture stops (*fourniture, plein-jeu, Zimbel,* etc.), also known as compound stops, are a grouping together of two, three or more ranks of pipes (usually but not necessarily of the principal type, though never of reeds) speaking a selection of the harmonics of the fundamental note. The essential and important difference between a mixture and a harmonic stop is that the latter (for example, as 12th or 15th) continues in unbroken note sequence right to the top of the keyboard, while a mixture will "break back" in the composition of its harmonics at frequent intervals. Thus the partials of a mixture, which on low C of the keyboard may be spread over a band beginning two octaves higher than 8-ft. pitch, will be gradually changed as the scale ascends, the higher partials being replaced by lower ones. The result is a brightening of the lower and tenor registers, a broadening of the middle and treble registers and—if the mixture is well voiced—a smoothing out of the upper registers. In the design and voicing of mixture stops lies the most difficult part of the organ builder's art, and experience proves that mixtures cannot be given satisfactory musical speech save on the lowest of wind pressures.

MANUALS

Great.—The great organ (Ger. *Hauptwerk,* Fr. *grand orgue*), as its name implies, represents a grouping of the most important stops of the organ. The typical great division of a large instrument will contain a principal chorus, the 8-ft. principal providing the basis. The double open principal 16 ft., the octave or principal 4 ft., the 12th $2\frac{2}{3}$ ft., the 15th 2 ft. and the mixture or mixtures are equally essential and may be likened to the root, branches and twigs of the principal trunk. The gedeckts (bourdon 16 ft., stopped diapason 8 ft., flute couverte 4 ft.) will be present, and in addition to their own solo usefulness will combine well with some of the upper principal stops. Open flute stops of several pitches may be included in the scheme under a diversity of shapes and names (clarabella, wald flute, melodia, etc.). Viols blend less readily with other stops, and thus may be little represented. Reeds are sometimes included; trumpets at 16-, 8- and 4-ft. pitches.

It may be remarked that the tonal individuality of an organ is set very largely by the character of the great ensemble, which musically—though illogically—might therefore be compared to the string section of a modern orchestra. National characteristics in organ design vary on this point. The German great is often designed on lines minimizing the proportion of the 8-ft. principal stops.

The French great tends to a thicker and more flutey tone for its 8-ft. basis, while the Spanish great sometimes appears to depend on a foundation of 8-ft. flute and viol tone.

Positive.—The division of the positive (Ger. *Oberwerk, Positiv* or *Brustwerk;* Fr. *positif*) comes next in musical importance. It may be placed above the great as an *Oberwerk,* below the great as a *Brustwerk* or as a *Rückpositiv* projecting from the gallery, quite apart from the main organ. Ideally it is a miniature great, of considerably smaller scale, with a gedeckt possibly replacing the 8-ft. diapason as the ensemble basis, and containing a reed such as the krummhorn. The positive should be totally unenclosed and placed well to the front (as stated above) where its tone will be distinguished from that of the great. The use of the positive is called for in practically all organ compositions, in episodic contrast to the great.

Swell.—The swell organ (Ger. *Schwellwerk,* Fr. *recit*), as implied by the name, is a grouping together of stops all enclosed within a large box. This box is faced on one or more sides with a set of shutters, not unlike the louvers of a venetian blind. By means of a swell pedal, connected to the shutters by mechanical or electrical means, the player may vary the volume of sound allowed to issue from the box. A typical swell division will contain a series of principal stops somewhat lighter than the great, flutes, salicionals and other viol-type stops, and some hybrids. A distinctive feature of the swell is the inclusion of a full representation of reed stops of the chorus type; an oboe, and a trumpet (trompette) or cornopean at 16-, 8- and 4-ft. pitches. The swell mixtures are

frequently designed to blend with these reeds.

Choir.—The choir organ is often included in place of the positive, though this is not a desirable substitution. In its general form it will have a collection, which ideally should be a complete ensemble, of mild flutes and viols, with the addition of a clarinet and perhaps other imitative reeds, the whole division being enclosed in a box on the same principle as the swell. Occasionally, large choir divisions will contain a complete flue and reed chorus.

Solo.—Whereas all divisions so far have been designed with the aim of building up a harmonious whole, the solo organ is frequently considered to be successful only in so far as it contains stops foreign to the rest of the instrument. On the solo manual are grouped imitative stops of all types, often representing extremes of scaling and voicing useful mainly in a solo capacity. On this manual, too, will be found the bombarde organ, a family of large scale reeds reinforced perhaps by mixtures. Here also will be placed the echo organ, or the antiphonal organ, gaining contrast by the placement of the pipes at a distance.

Pedal.—Included in the pedal organ should be stops continuing downward all types of tone included on the manuals, so that a suitable bass may be found for any stop, or combination of stops, piano to fortissimo. The pedal stops are pitched an octave lower than those of the same name on the manuals. Thus the characteristic pitch is 16 ft., rather than 8 ft., and the length of low C on the pedal open principal will be 16 ft. A well-equipped pedal organ will include stops of various pitches from perhaps 32 ft. to 4 ft., 2 ft. or even 1 ft. and some mixture stops. In general, the pedal organ should hold its own against the full manual divisions without having to be coupled to them, and it should be able to carry a melodic line at any of several pitches independently of the manuals. Reed stops are particularly effective on the pedal and may be present at unison pitches from 32 ft. to 2 ft. They may often be played with fine effect against the full flue ensembles of the manuals.

Wind Chests, Blowing Apparatus.—In addition to supporting the pipes, a wind chest contains the mechanism for distributing wind to each pipe. The usual chest is a large wooden box divided into as many longitudinal compartments as there are stops to be accommodated. Over its top surface are the upper boards on which the pipes rest, the foot of each pipe fitting exactly into a hole through which wind from the chest may pass, as permitted by a pallet or valve. Above the upper boards are the rack boards, which support the pipes at a point several inches higher and thus maintain their vertical position.

The supply of air to the wind chest is delivered by a rotary blower, spun at high speed by an electric motor. Air under pressure may also be provided by the operation of large bellows, by hand or by mechanical means. From one of these originating sources, the wind passes to a reservoir—a shallow box which can expand upward, concertina fashion, but contained by springs or by weights on the top. The reservoir smoothes out the supply of air from the primary source and passes it along to the wind chest under an even and predetermined pressure.

An organ is said to have a certain number of inches of wind pressure. The figure is determined by applying the wind supply, from a pipe hole of the wind chest, to one side of two even columns of water in an anemometer, or open U-shaped glass tube. If the two columns are displaced to the extent of say, $2\frac{1}{2}$ in., the pipes are said to be speaking on $2\frac{1}{2}$ in. of wind pressure.

The interior mechanism of the wind chest consists in principle of a valve, or pallet, at the foot of each pipe; with which the player, through connecting mechanisms between the keyboards and the wind chest, may by the playing of the key admit or shut off air to that pipe. There have been four general types of such organ action. All older organs depended on a mechanical or tracker action, consisting of a series of rods and levers by which the actual physical motion of the finger and the key was transmitted, pulling down the pallet under the pipe. Certain musical advantages are claimed for this method as well as a basic simplicity, and it still has a certain vogue. The 19th century saw the invention of the Barker lever, a small pneumatic bellows which by expansion assisted the player in the chain of effort and movement. Electropneumatic action, coupled with the Pitman chest is by far the most widely used method among organ builders of the 20th century, though other electropneumatic actions have been evolved, and some all-electric actions have been devised.

As the name implies, the electropneumatic action depends for its motive power both on electricity and wind pressure. If we may regard all intermediate mechanisms which join the fingers of the organist with the sounding of the pipes as links in a chain, the first such link will be the completion of an electric circuit by the depression of a key at the console. This actuates an electric magnet which in turn opens a small valve. This allows pneumatic pressure to pull down the pallet underneath the pipe, allowing pressure wind in the chest to pass up through the foot of the pipe and to cause the pipe to speak.

The method of the stop action, by which any one rank of pipes, or any combinations of ranks, may be played at will, is readily understood by considering the method employed in the older slider chests. Underneath each row of pipes on these chests is a strip of wood (or slider) bored with a row of holes corresponding to the foot holes of the pipe. In this position, the stop is "on," but by levers extending from the stop knobs at the console the board may be pulled slightly to one side, so that the holes do not coincide and the passage of air from the wind chest past the pallets to the pipes will be blocked.

In the Pitman chest, sliders are not employed, and the same end is achieved by the provision of an individual valve for each pipe, these valves being controlled by electric or electropneumatic means from the stop knobs or stop tablets at the console.

Console.—At the console the player may have before him several manuals, each controlling one or more divisions of the organ. From the lower to the upper manuals the sequence is usually: positive and/or choir; great; swell; solo (bombarde, orchestral, echo, antiphonal). Beneath his feet is the pedal board, with keys similar to those of the manuals but of larger size, to be played by the feet. To the right and left on the stop jambs, and possibly in front above the top manual, are the stops (knobs or tablets) ranged according to their groupings on the manuals. With a knob pulled out, or a tablet tilted down, a stop is said to be on (*i.e.*, at the ready). Certain stops are called couplers. These are not connected to pipes, but provide for the coupling of almost any one manual to another, either at unison or at sub- or superoctave pitch. Moreover, some manuals may be duplicated on themselves at sub- or superoctave pitches, though this is a device sometimes expedient but rarely desirable and should not be necessary in the ensemble of a well-voiced instrument. Buttons under or above the manuals, which may be preset or adjustable in their action, enable the player to pull out or push in stops and couplers en masse or in various groupings. These buttons are frequently duplicated by toe studs placed just above the pedal board. Above and to the centre of the pedal board will also be found balanced "expression" pedals, controlling the opening and closing of the shutters of enclosed divisions. The crescendo pedal, usually to the right of any "expression" pedals, is a rough and ready means of bringing on the stops in sequence by electrical means, without actuating the stop knobs. German organs have a roller device (*Rollschweller*) which achieves the same end. Mechanical connections in a tracker action necessitate placing the console as near to the wind chests as possible, but with modern action it is an advantage to be able to place the console at a convenient distance from the organ, where the player may better judge the balance of sound, connection between console and wind chest being made by electric cable.

BY COURTESY OF (1-4) THE SKINNER ORGAN COMPANY, (5) THE HAMMOND ORGAN

PARTS OF A MODERN ORGAN

1. Large organ at Finney Chapel, Oberlin College, Oberlin, Ohio, showing casework and display pipes. The console is in the foreground
2. Same organ shown in fig. 1, with casework and display pipes removed, showing interior, with manual and pedal pipes and swell boxes
3. Giant pipes known as Bombardes, set up in the factory for voicing and tuning
4. View of a standard four manual console, similar to the instrument shown in fig 1
5. A modern electric organ, the two units of which shown are the entire instrument. The organ can be played the moment it is plugged into the ordinary household electric circuit. Its tones are created by electrical impulses instead of by air pressure. When a playing key is depressed an electrical wave, of the same shape as the sound wave for that key, is generated within the console and passed to the tone cabinet where it is amplified into audible sound. This modern electrical instrument is said to achieve the quality and rich variety of the great organs.

ORGANIC SENSATIONS, a term for all the bodily sensations except those derived from the skin. In addition to the four special senses, sight, hearing, taste and smell, there is the common sensibility or somaesthesia, which includes cutaneous sensations and also organic sensations. Organic sensations may be subdivided into kinaesthetic sensations, vestibular, or static, sensations and visceral sensations. The deep sensibility that comes from the tissues immediately beneath the skin may also be included under this class term.

Kinaesthetic sensation, so named because it mediates the perception of bodily movement as well as the perceptions of weight, resistance and posture, arises in the muscles, tendons and joints, all of which are supplied with sense organs. Its nervous mechanism has also been called the proprioceptive system, whose function it is to furnish the sensory clues necessary for the control of precise movement.

The vestibular, or static, sense has to do with the maintenance of balance and of bodily position and with the perception of rotation. It arises in the vestibule and the semicircular canals of the inner ear.

The otolith organs in the vestibule mediate the perception of linear acceleration, up and down, forward and backward, and also function in the maintenance of bodily posture. The canals mediate the perception of rotation and dizziness.

The visceral sensations constitute the basis for such experiences as hunger, nausea, appetite and sexual urge.

The experience of gnawing hunger depends on certain slow contractions of the stomach which stimulate sense organs in the gastric tissues.

(E. G. BOR.)

ORGANOMETALLIC COMPOUNDS are chemical substances containing a metal or metalloid in direct association with one or more hydrocarbon radicals. These compounds never arise by natural processes in the vegetable and animal kingdoms, being produced synthetically by the art of the chemist. They have played an important part in the development of modern chemistry, and among them are several substances of great practical utility.

Lead tetraethyl (*see* below), a most effective antidetonant in motor gasoline, or petrol, and salvarsan, a specific remedy in syphilis, are two outstanding examples of organometallic compounds of proven worth.

Included in this group of carbon compounds are the organic derivatives of magnesium known after their discoverer as Grignard reagents (*q.v.*).

The application of these reagents in chemical synthesis has proved to be without doubt one of the most fruitful and far-reaching advances in practical organic chemistry since the end of the 19th century.

Brief references to organometallic compounds have been given under the headings of certain of the metals and metalloids, and the present article affords a general survey of the whole group of compounds.

The arrangement adopted below follows the natural sequence of the elements according to the periodic law (*q.v.*).

Group I.—Although organosodium compounds were prepared as early as 1858 (J. Wanklyn), the existence and properties of these substances remained doubtful until early in the 20th century (W. Schlenk and co-workers, 1913–17). Lithium ethyl, $Li.C_2H_5$, is prepared by the action of metallic lithium on mercury diethyl; it crystallizes from benzene or high-boiling petroleum in colourless, six-sided plates melting at 95° C. Lithium methyl, $Li.CH_3$, and lithium phenyl, $Li.C_6H_5$, are crystalline powders obtained by double decomposition between lithium ethyl and mercury dimethyl and diphenyl respectively (Schlenk and J. Holtz, 1917). More recently, lithium alkyls and aryls have been prepared from lithium metal and alkyl and aryl halides (K. Ziegler, 1930; H. Gilman, 1932). Sodium triphenylmethyl, $Na.C(C_6H_5)_3$, is obtained by the action of 1% sodium amalgam on triphenylchloromethane, $(C_6H_5)_3CCl$, dissolved in dry ether in an atmosphere of oxygen-free nitrogen. The product is a brownish-red solid. The simpler sodium alkyls are prepared by the action of sodium metal on a mercury alkyl (Schlenk) or zinc alkyl (A. v. Grosse, 1926). Sodium methyl, $Na.CH_3$, is a white powder which burns in air with explosive rapidity. Sodium ethyl, $Na.C_2H_5$, sodium *n*-propyl, $Na.C_3H_7$, and sodium phenyl, $Na.C_6H_5$, are colourless solids having similar properties. Cuprous phenyl, $Cu.C_6H_5$, obtained by the interaction of cuprous iodide and magnesium phenyl bromide in ethereal solution, is a white powder decomposing at 80° C. into copper and diphenyl. Silver phenyl, $Ag.C_6H_5$, an even more unstable substance obtained from phenyl magnesium bromide and silver bromide, is a yellow solid, exploding on rubbing, on gentle warming or on treatment with acids. An ethereal solution of auric bromide and magnesium ethyl bromide yields on evaporation colourless crystalline diethylauric bromide, $(C_2H_5)_2AuBr$, melting at 58° C. and exploding at 70° C. Bromine in chloroform converts this monobromide into the ruby-red ethylauric dibromide, $C_2H_5.AuBr_2$ (W. J. Pope and C. S. Gibson, 1907).

Group II.—The organic derivatives of beryllium are referred to under this metal and the organomagnesium compounds are described in a special article. (*See* GRIGNARD REAGENTS.) The organozinc compounds were discovered by E. Frankland in 1849, and from his study of similar compounds he was led to the conception of chemical valency. In conjunction with B. F. Duppa (1863) he applied them in many organic syntheses which were extended by G. A. Freund (1861), A. Butlerow (1867) and others. Zinc dimethyl (b.p. 46° C.) and zinc diethyl (b.p. 118° C.) are colourless malodorous liquids, spontaneously inflammable in air. They are prepared by distilling the products of the interaction of methyl and ethyl iodides with a zinc copper couple. More recently zinc phenyl bromide, as a crystalline dietherate (E. Blaise, 1911), and zinc diphenyl (A. Job and R. Reich, 1923) have been obtained by the interaction of magnesium phenyl bromide and anhydrous zinc chloride. The cadmium dialkyls (dimethyl, diethyl, dipropyl, dibutyl, etc.) are procurable in good yields from anhydrous cadmium bromide and the appropriate magnesium alkyl bromide. Cadmium dimethyl, $Cd(CH_3)_2$ is a colourless liquid boiling at 105° C. (E. Krause, 1917). Mercury possesses a remarkable capacity for combination with the carbon of hydrocarbon groups and of organic radicals in general. Sodium amalgam acts directly on ethyl iodide and bromobenzene, giving respectively mercury diethyl, $Hg(C_2H_5)_2$ (b.p. 159° C.), and mercury diphenyl, $Hg(C_6H_5)_2$ (m.p. 120° C.). With certain reactive substances such as aromatic bases or phenols, mercury derivatives are obtained merely by boiling with mercuric acetate; aniline yields *o*- and *p*-amino-phenylmercuriacetates, whereas *m*-toluidine takes up two and even three mercuriacetate residues. Phenol gives rise to *o*- and *p*-hydroxyphenylmercuriacetates and hydroxyphenyl-2:4-dimercuriacetate. In addition to the foregoing processes, organomercury compounds are conveniently prepared through the agency of Grignard reagents. Mercury dimethyl, a colourless liquid boiling at 89–92° C., is obtained from magnesium methyl iodide and mercuric chloride, and the homologous mercury dialkyls are prepared similarly.

Group III.—Aluminum trialkyls and triaryls have been recorded, and the production of these substances is facilitated by the use of Grignard reagents. Magnesium ethyl bromide and anhydrous aluminum chloride interact in dry ether to produce aluminum triethyl etherate, $4Al(C_2H_5)_3,3(C_2H_5)_2O$, as a colourless mobile liquid boiling at 112° C./16mm. It fumes in air, takes fire spontaneously, and is decomposed explosively by cold water (E. Krause and B. Wendt, 1923). Aluminum diethyl iodide (b.p. 118–120° C./4 mm.) and aluminum ethyl diiodide (m.p. 35–37° C.; b.p. 158–160° C./4 mm.) were obtained by V. Grignard and R. L. Jenkins (1925) from the liquid product of the interaction of aluminum and ethyl iodide.

Organic derivatives of indium and thallium are obtainable through the Grignard reagents. Thallic bromide, but not thallous bromide, yields both dialkyl and diaryl compounds. Thallic dimethyl bromide, $(CH_3)_2TlBr$, forms silvery-white leaflets (R. J. Meyer and A. Bertheim, 1904), whereas thallic diphenyl bromide, $(C_6H_5)_2TlBr$, is obtained in colourless transparent microscopic needles (D. Goddard and A. E. Goddard, 1922).

Group IV.—Organic derivatives are known of silicon (*q.v.*), germanium (*q.v.*), tin and lead. The most common and stable organolead compounds are the lead tetraalkyls and tetraaryls, which are obtained by interaction of lead chloride or lead bromide with the appropriate Grignard reagent,

$$4\ RMgBr + 2\ PbBr_2 = PbR_4 + Pb + 4\ MgBr_2.$$

Lead tetramethyl, $Pb(CH_3)_4$, lead tetraethyl, $Pb(C_2H_5)_4$, and other lead tetraalkyls have been prepared in this manner, as have the tetraaryls such as lead tetraphenyl, $Pb(C_6H_5)_4$. Treatment of these compounds with acids or halogens converts them to alkyl lead salts, such as $(C_2H_5)_3PbCl$ and $(C_6H_5)_2Pb(NO_3)_2$. Lead tetraalkyls containing different alkyl groups are prepared by reaction of alkyl lead halides with a Grignard reagent containing a different alkyl group (G. Grüttner and E. Krause, 1917), or by interaction of two different lead tetraalkyls in the presence of aluminum chloride (G. Calingaert and co-workers, 1939). The lower lead tetraalkyls are relatively stable, colourless, volatile liquids, while the lead tetraaryls are colourless solids. Organolead compounds such as dilead hexamethyl, $(CH_3)_3Pb.Pb(CH_3)_3$, dilead hexaphenyl, $(C_6H_5)_3Pb.Pb(C_6H_5)_3$, and lead diphenyl, $Pb(C_6H_5)_2$ have also been prepared; on being heated these decompose to the corresponding PbR_4 compounds and metallic lead.

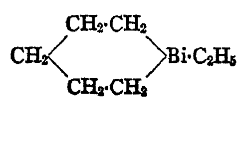
The commercially important lead tetraethyl is now manufactured (in the U.S.A. and other countries) by the action of ethyl chloride under pressure on a powdered alloy of lead and sodium contained in an autoclave. The lead tetraethyl is steam distilled from the reaction mass, leaving sodium chloride and metallic lead as the by-products. It is a colourless liquid, stable in air, soluble in gasoline, and quite volatile, although it decomposes at temperatures below its boiling point. For use as an antidetonant, it is added to gasoline in quantities not exceeding 3.0 cc. per gallon; a small quantity of ethylene dibromide, and sometimes ethylene dichloride, is added to prevent the formation of lead deposits in the engine.

The preparation and properties of organotin compounds are very much like those of organolead compounds. Stannous chloride and magnesium ethyl bromide give tin diethyl, $Sn(C_2H_5)_2$, as an oxidizable oil insoluble in water (P. Pfeiffer, 1911), whereas tin diphenyl, $Sn(C_6H_5)_2$, a bright yellow powder melting at 130° C. to a dark red liquid, is obtained from stannous chloride and magnesium phenyl bromide. When excess of Grignard reagent is used, this diaryl compound loses part of its tin and passes into ditin hexaphenyl, $3Sn(C_6H_5)_2 = Sn + (C_6H_5)_3Sn.Sn(C_6H_5)_3$, obtained in colourless plates melting at 237° C. (E. Krause and R. Becker, 1920). Tin tetramethyl, $Sn(CH_3)_4$, and tin tetraethyl $Sn(C_2H_5)_4$, boiling at 78° C. and 175° C. respectively, are prepared in good yields from stannic chloride and the appropriate Grignard reagents; in the latter case triethylstannic chloride, $(C_2H_5)_3SnCl$, is obtained as a by-product.

Magnesium benzyl chloride and stannic chloride give tribenzylstannic chloride, $(C_7H_7)_3SnCl$, (m.p. 143–145° C.) and tin tetrabenzyl (tetrabenzylstannane), $Sn(C_7H_7)_4$, (colourless needles, m.p. 42–43° C.). The former compound when acted on by chlorine furnishes dibenzylstannic chloride $(C_7H_7)_2SnCl_2$ in colourless crystals melting at 163–4° C. (T. Smith and F. S. Kipping, 1912).

Group V.—Certain more outstanding examples of organic derivatives of arsenic and antimony are described in the articles on these metalloids. Both trialkyl- and triaryl-bismuthines have long been known and were formerly prepared by the interaction of alkyl or aryl halides and sodium or potassium bismuthides.

The use of Grignard reagents has considerably enlarged the bismuth series of organic compounds. Diphenyl-α-naphthylbismuthine and tri-α-naphthylbismuthine (melting points 118–119° C. and 235° C.) have been prepared in this way (F. Challenger, 1914), and a cyclic bismuth compound, ethyl*cyclo*bismuthopentane has been prepared by the successive action on bismuth tribromide of magnesium ethyl bromide and the dimagnesium compound of 1:5–dibromopentane (G. Grüttner and M. Wiernik, 1915); it is a yellow viscous oil boiling at 108–112° C./18–20 mm. with an unpleasant odour and oxidizing rapidly in air.



Group VI.—Organic derivatives of selenium (*q.v.*) and tellurium (*q.v.*) are mentioned under these headings. A remarkable series of organic chromium compounds has been described by F. Hein (1919–24), who by the action of magnesium phenyl bromide either on chromyl chloride or on anhydrous chromic chloride obtained chromium pentaphenyl bromide, $Cr(C_6H_5)_5Br$, an orange-brown amorphous substance converted by alcoholic potash into chromium pentaphenyl hydroxide, $Cr(C_6H_5)_5OH,4H_2O$, crystallizing in golden-yellow leaflets. This basic hydroxide on treatment with acids loses a phenyl group giving rise to salts of the general type $[Cr(C_6H_5)_4]X$ (where X is the acid radical). Moreover, the mother-liquors from chromium pentaphenyl hydroxide contain chromium triphenyl hydroxide, which gives the corresponding salts $[Cr(C_6H_5)_3]X$. These organic derivatives indicate that chromium has valencies of 6, 5 and 4.

Group VIII.—Very few organometallic compounds of the metals of this group are known. Apart from some organoiron compounds, the only organometallic compounds isolated have been some platinum compounds. Ethyl iron chloride, C_2H_5FeCl, has been prepared by interaction of ethyl zinc iodide and ferrous chloride (A. Job and R. Reich, 1922). Phenyl iron iodide, $(C_6H_5)FeI$, has also been prepared from ferrous iodide and phenyl zinc iodide (G. Champetier, 1930). Trimethyl platinum iodide, $(CH_3)_3PtI$, has been obtained by interaction of platinum chloride and magnesium methyl iodide. The product, a yellow crystalline solid, is converted by silver oxide to trimethyl platinum hydroxide, $(CH_3)_3PtOH$. Solution of the latter in nitric acid gives the nitrate, $(CH_3)_3PtNO_3$. The corresponding chloride, $(CH_3)_3PtCl$, crystallizes from chloroform in colourless rhombic dodecahedra (W. J. Pope and S. J. Peachy, 1909). Platinum tetramethyl, $Pt(CH_3)_4$, has been prepared from trimethyl platinum iodide and sodium methyl, and diplatinum hexamethyl, $(CH_3)_3Pt.Pt(CH_3)_3$, has been obtained by heating trimethyl platinum iodide with powdered potassium in dry benzene (H. Gilman and M. Lichtenwalter, 1936).

(G. T. M.; G. Ct.)

ORGANON, the name given to Aristotle's logical treatises (Gr. ὄργανον, instrument). They are so called because logic is itself neither a speculative science nor a practical art in the ordinary sense, but an aid or instrument to all scientific thought. Francis Bacon gave to his own treatise the name *Novum Organum* in the belief that he had discovered a new inductive logic.

ORGY, a term originally denoting the secret rites or ceremonies connected with the worship of certain deities. The word is derived from Lat. *Orgia*, Gr. ὄργια, a post-Homeric word used of the secret rites of Demeter (*q.v.*), at Eleusis, of the Cabeiri, Orpheus and Eumolpus (*qq.v.*), but most commonly of the rites of Dionysus-Bacchus, with their dedications and purifications. The word has been connected with *ἔργω = ἔρδω, ῥέζω, in the sense of performing sacred rites; Lat. *operari*, to perform sacrifice.

The Dionysiac orgies, which were restricted to women, were celebrated in the winter among the Thracian hills or in spots remote from city life. The women met, generally at night, clad in fawn skins, with hair dishevelled, swinging the thyrsus and beating the cymbal; they danced and worked themselves up to a state of mad excitement. A bull, the representative of the god, was torn in pieces by them as Dionysus-Zagreus had been torn. The women tore the bull with their teeth, and the eating of the raw flesh was a necessary part of the ritual. The most famous festival of the kind was the τριετηρίς, the triennial festival, celebrated on Parnassus by the women of Attica and Phocis. The

celebrants were called Maenads or Bacchae. The wild dances and other "orgiastic" ceremonies have given rise to the use of the word "orgy" for any wild revel or festivity. (*See* DIONYSUS and MYSTERY.)

ORIBI or **OUREBI**, a small South African antelope (*Ourebia ourebi*), standing about 24 in. at the shoulder, and characterized by a bare glandular spot below the ear, the upright horns of the bucks, which are ringed for a short distance above the face, and the tufted bushy tail. The name is extended to include the other members of the same genus.

ORIEL, in architecture, a projecting bay window carried by corbels or mouldings. It is usually polygonal or semicircular in plan, but at Oxford, in some of the colleges, there are examples which are rectangular and rise through two or three storeys. In Germany it forms a favourite feature, and is sometimes placed at the angle of a building, carried up through two or three floors and covered with a lofty roof. The oriel is also said to have been provided as a recess for an altar in an oratory or small chapel. In the 15th century oriels came into general use, and are frequently found over entrance gateways.

The earliest meaning of the word seems to be a gallery, portico or corridor, and the application of the term to a particular form of window apparently arose from such a window being in an "oriel." In Cornwall "orrel" is still used of a balcony or porch at the head of an outside staircase leading to an upper storey in a fisherman's cottage. The name of Oriel college, Oxford, comes from a tenement known as Seneschal Hall or La Oriole, granted to the college in 1327. (*See* BAY; WINDOW.)

ORIENTAL COOKERY is characterized by the use of many condiments, often making the food very "hot," and by the use of very sweet dishes. In general, the Orient prefers main dishes in which many food materials have been combined into one appetizing whole, and this means cutting into small pieces. Confucius refused to eat food that was not "chopped up properly," and also ruled that there must never be more flesh food than vegetables in the mixture. A Japanese rule calls for the five tastes of sweet, salt, sour, bitter and acrid in each meal, and another for something in each from both sea and mountain. The most widely used meat is lamb or mutton. In China pork is common. The *kebob* of Turkey and India is meat, fish or poultry cut small and strung on a skewer, often with alternating slices of vegetable. It is usually broiled. *Pilaf* or *pilau*, the national dish of Turkey and much eaten in India, is a dish of rice (usually browned in fat before cooking in stock), to which flesh foods or vegetables or both are added, either cooked with the rice or served on it, and the mixture highly seasoned. The Armenian *herissa* and the Arabian *couscous* are similar dishes made with cracked wheat instead of rice. The Turkish *dolma* is a vegetable stuffed with rice and minced meat or olive oil. Vine leaves are also used for this. Birds, domestic and wild, vary the diet. Fish and shellfish furnish more of the flesh food than does meat, being in most places abundant and cheap. All flesh foods and vegetables are preserved by drying as well as in other ways. "Bombay duck" is dried salted fish. Flesh foods eaten in the East not used in the West include buffalo, cat, dog, field rat, snake, lizard, beetle, cockroach, larvae, ant, worm, shark fin and whale, some of these being held to be great delicacies.

For fat, India uses *ghee* (clarified butter), China peanut oil, Turkey and adjacent countries olive oil, and many sesame oil. Eggs are cooked in many ways. Bread is not in as general use as in the Occident, though in Japan it is growing in popularity. The *chapati* of the Indian peasant is a thin wafer made of whole wheat flour, "pan" fried in *ghee*. The main vegetable food of the Orient is rice, which is almost everywhere served with every meal, and is generally cooked in stock. Cracked wheat, barley, buckwheat, sesame and the millets are used in some countries. Noodles are eaten, and Italian pastes, though not native, are now in Eastern markets. Milk is used in Turkey and kindred countries when curdled (*matzoun*) as a beverage and in sauces. Tea is the universal beverage of the Orient, and in some countries coffee is common. Turkish coffee is made from the following formula: For four small cups, ¾ cup water, 3 teaspoons sugar, 3 teaspoons pulverized coffee. Melt the sugar in the water over the fire, remove from fire, add coffee, stir one minute, return to fire and bring to boiling point three or four times. This is not strained, but sipped from the cup after the coffee has settled to the bottom.

Fruits are usually cooked, except that dates, the staple food of the lands of the Near East, are rarely cooked except in puddings and confections. In China pineapple is often cooked with chicken and other meats. Pastries, sweet with sugar syrup and often with nuts, or a sweet fruit compote, are the usual ending for a Turkish meal. The Chinese and Japanese use sweet cakes, confections and puddings, or cooked or preserved fruits. Salads are much eaten in the Near East, usually of a combination of vegetables and perhaps fruits. Seasonings used in the Orient not common in the Occident include cummin, saffron, coriander seed, tamarind, chilis in variety, curry powder and soy sauce. Vegetable foods form the greater part of the diet.

The most famous dish of India is the curry, in which material cooked with curry powder or in a curry sauce is served in a ring of rice. The epicure insists on curries made from spices ground fresh each day, but curry powder and essence may be made ahead in the home or may be bought bottled. A good formula for curry sauce, hot enough for the average Western taste, but not for that of India, uses 2 tablespoons minced onion, fried a little in ¼ cup butter, 1½ tablespoons curry powder, mixed to a paste with a little of 2 cups of stock or milk, 2 teaspoons curry essence, ¼ teaspoon salt, 1 tablespoon rice flour, 1 cup cocoanut or almond milk (made by soaking an hour in 1 cup milk, ½ cup freshly ground cocoanut or blanched almonds ground fine, and used with or without straining), 1 teaspoon scraped green ginger, 1 teaspoon currant jelly. The meat, fish, shellfish, poultry or vegetables are cooked in the sauce. With a curry is served chutney, a sauce or conserve made of sweet and sour fruits and vegetables, highly spiced.

Chinese and Japanese food are similar, though not the same. Young bamboo sprouts, bean sprouts, water chestnuts, dried mushrooms and *pe-tsai* (Chinese cabbage) are favourite vegetables. The soy bean is used not only in soy sauce, but for the delicate bean curd that adds an agreeable texture and flavour to so many dishes. The famous bird's nests of China are used in dishes with chicken and pigeon as well as for soup. They are a luxury, as are the equally famous ancient eggs. Almonds are used in many combinations.

Chop suey is a dish unknown in China. The Japanese serve many foods cooked in deep fat after being dipped in a very delicate batter.

In Japan the diner in a restaurant often cooks his own food in an iron skillet set on the dining table. (I. E. L.)

ORIENTATION, a term expressing the angular relation of any object to the points of the compass; in architecture, used to express the relation of the main dimensions of a building, with reference to the points of the compass, and especially with reference to the east. In Mesopotamia and Egypt, as well as in primitive Central America, orientation of buildings was common from an early date, with important features, entrances, passages and the like designed to point in the direction of the rising sun. In north Europe the same custom evidently prevailed, as Stonehenge, near Salisbury, England, is carefully orientated. Many Greek temples were also designed to face the rising sun.

In the earliest Christian basilicas at Rome, the apse was placed at the west end, so that the priest who served the altar from behind, facing the congregation, himself faced the east and the rising sun. This orientation has sometimes been traced to the influence of the churches of the Holy Sepulchre at Jerusalem and of the Nativity at Bethlehem. It is more probable, however, that this orientation was due to an underlying tradition whose roots go far back beyond the origin of Christianity.

In St. Sophia, Constantinople, and all the Byzantine churches, the apse was placed at the east end, and the same custom obtains in the early churches in Syria and the Coptic churches in Egypt. During the 6th and 7th centuries this orientation gradually came into use in Italy and the west generally. Orientation of this type, with the apse or altar toward the east, is generally carefully observed in Spain, Germany and England, and

less carefully in France and Italy. It is so common, however, that in an architectural or ecclesiastical description of a church building, the "east end" is always the end with the apse or altar. In Mohammedan mosques the mihrab or prayer niche is so placed that the worshipper looks towards Mecca.

Orientation is an important consideration in the placing of any building, as exposure to the sun, or lack of it, prevailing winds and similar facts in climate must be considered in designing a building for any purpose. Thus in the northern temperate zone, living rooms are usually arranged to get large amounts of south light; studios are arranged with north light, and, in general, buildings like schools, with rooms on both sides of a corridor, are placed, if possible, with the corridor running north and south, so that the rooms on both sides may receive the sun.

ORIENTE or La Region Oriental, a large undefined territory of Ecuador, comprising all that part of the republic lying east of the Andes. Pop. (1950 census) 31,989. The region was divided into two provinces, Napo-Pastaza and Santiago-Zamora. A recurrent border war was fought with Peru in 1941, involving a contested area of more than 150,000 sq.mi. At the Rio de Janeiro conference in Jan. 1942, Peru and Ecuador agreed to submit the dispute to a boundary commission comprised of representatives from their own countries and the United States, but ten years later the border had still not been delineated.

ORIGEN (*c.* 185–*c.* 254), the most distinguished and most influential of all the theologians of the ancient church, with the possible exception of Augustine.

Origen was born, perhaps at Alexandria, of Christian parents in the year 185 or 186. His father Leonidas gave him an excellent education. At a very early age, about the year 200, he listened to the lectures of Pantaenus and Clement in the catechetical school. This school, of which the origin (though assigned to Athenagoras) is unknown, was the first and for a long time the only institution where Christians were instructed simultaneously in the Greek sciences and the doctrines of the holy Scriptures. Asia Minor and the West developed the strict ecclesiastical forms by means of which the church closed her lines against heathenism, and especially against heresy; in Alexandria Christian ideas were handled in a free and speculative fashion and worked out with the help of Greek philosophy. The line between heresy and orthodoxy was less rigidly drawn there than at Ephesus, Lyons, Rome or Carthage.

In the year 202 a persecution arose, in which the father of Origen perished. Origen began about the same time to earn his bread by teaching; and in 203 he was placed, with the sanction of the bishop of Demetrius, at the head of the catechetical school. He regularly attended the lectures of Ammonius Saccas, and made a thorough study of the books of Plato and Numenius, of the Stoics and the Pythagoreans. At the same time he endeavoured to acquire a knowledge of Hebrew, in order to be able to read the Old Testament in the original. His manner of life was ascetic; the sayings of the Sermon on the Mount and the practical maxims of the Stoics were his guiding stars. Four oboli a day, earned by copying manuscripts, sufficed for his bodily sustenance. A rash resolve led him to castrate himself that he might work unhindered in the instruction of women.

He commenced his great work on the textual criticism of the Scriptures; and at the instigation of his friend Ambrosius, who provided him with the necessary amanuenses, he published his commentaries on the Old Testament and his dogmatic investigations. He worked at Alexandria for 28 years (till 231–232). This period, however, was broken by many journeys to Rome, to Arabia, to Antioch, and, in 216, when the imperial executioners were ravaging Alexandria, to Palestine. There the bishops of Jerusalem and Caesarea got him to deliver public lectures in the churches. In the East, especially in Asia Minor, it was still no unusual thing for laymen, with permission of the bishop, to address the people in the church. In Alexandria, however, this custom had been given up, and Demetrius took occasion to express his disapproval and recall Origen to Alexandria.

Probably the bishop was jealous of the high reputation of the teacher; and a coolness arose between them which led, fifteen years later, to an open rupture. On his way to Greece (apparently in the year 230) Origen was ordained a presbyter in Palestine by his friends the bishops. This was undoubtedly an infringement of the rights of the Alexandrian bishop; at the same time it was simply spite on the part of the latter that had kept Origen so long without orders. Demetrius convened a synod, at which it was resolved to banish Origen from Alexandria. A second synod, composed entirely of bishops, determined that Origen must be deprived of his status as a presbyter. This decision seems to have been justified by referring to the self-mutilation of Origen and adducing objectionable doctrines which he was said to have promulgated. No formal excommunication of Origen appears to have been decreed; the sentence of deprivation was approved by most of the churches, in particular by that of Rome. At a later period Origen sought to vindicate his teaching in a letter to the Roman bishop Fabian, but, it would seem, without success.

In these circumstances Origen retired from Alexandria (231–232) to Palestine, where his condemnation had not been acknowledged by the churches. He settled in Caesarea, and established a flourishing school there. Enthusiastic pupils sat at his feet (see the *Panegyric* of Gregory Thaumaturgus), and the methodical instruction which he imparted was famous all over the East. He made frequent journeys. He was for two years together at Caesarea in Cappadocia, where he was overtaken by the Maximinian persecution; here he worked at his recension of the Bible. We find him again in Nicomedia, in Athens, and twice in Arabia. He was called there to combat the unitarian christology of Beryllus, bishop of Bostra, and to clear up certain eschatological questions. As he had formerly had dealings with the house of Alexander Severus, so now he entered into a correspondence with the emperor Philip the Arabian and his wife Severa. But through all situations of his life he preserved his equanimity, his keen interest in science, and his indefatigable zeal for the instruction of others. In the year 250 the Decian persecution broke out, Origen was arrested, imprisoned and maltreated. But he survived these troubles and lived a few years longer in active intercourse with his friends. He died, probably in the year 254 at Tyre.

Writings.—Origen is probably the most prolific author of the ancient church. "Which of us," asks Jerome, "can read all that he has written?" The number of his works was estimated at 6000, but that is certainly an exaggeration. Owing to the increasing unpopularity of Origen in the church, a comparatively small portion of these works have come down to us in the original. We have more in the Latin translation of Rufinus; but this translation is by no means trustworthy, since Rufinus, assuming that Origen's writings had been tampered with by the heretics, considered himself at liberty to omit or amend heterodox statements. Origen's real opinion, however, may frequently be gathered from the *Philocalia*—a sort of anthology from his works prepared by Basil the Great and Gregory Nazianzenus. The fragments in Photius and in the *Apology* of Pamphilus serve for comparison. The writings of Origen consist of letters, and of works in textual criticism, exegesis, apologetics, dogmatic and practical theology.

1. Eusebius (to whom we owe our full knowledge of his life) collected more than a hundred of Origen's letters, arranged them in books, and deposited them in the library at Caesarea (*H.E.* vi. 36). In the church library at Jerusalem (founded by the bishop Alexander) there were also numerous letters of this father (Euseb. *H.E.* vi. 20). But unfortunately they have all been lost except two—one to Julius Africanus and one to Gregory Thaumaturgus. There are, besides, a couple of fragments.

2. Origen's textual studies on the Old Testament were undertaken partly in order to improve the manuscript tradition, and partly for apologetic reasons, to clear up the relation between the LXX and the original Hebrew text. The results of more than twenty years' labour were set forth in his *Hexapla* and *Tetrapla*, in which he placed the Hebrew text side by side with the various Greek versions, examined their mutual relations in detail, and tried to find the basis for a more reliable text of the LXX. The *Hexapla* was probably never fully written out, but excerpts were made from it by various scholars at Caesarea in the 4th century; and thus large sections of it have been saved. He worked at the text of the New Testament, although he produced no recension.

3. The exegetical labours of Origen extend over the whole of the Old and New Testaments. They are divided into *Scholia* (σημειώσεις, short annotations, mostly grammatical), *Homilies* (edifying expositions grounded on exegesis), and *Commentaries* (τόμοι). In the Greek original only a very small portion has been preserved; in Latin translations, however, a good deal. The most important parts are the homilies on Jeremiah, the books of Moses, Joshua and Luke, and the commentaries on Matthew, John and Romans. With grammatical precision, antiquarian learning and critical discernment Origen combines the allegorical method of interpretation—the logical corollary of his conception of the inspiration of the Scriptures. He distinguishes a threefold sense of scripture, a grammatico-historical, a moral and a pneumatic—the last being the proper and highest sense. He thus set up a formal theory of allegorical exegesis, not quite extinct in the churches even yet, and in his own system of fundamental importance.

4. The principal apologetic work of Origen is his book κατὰ Κέλσου (eight books), written at Caesarea in the time of Philip the Arabian. It has been completely preserved in the original. This work is invaluable as a source for the history and situation of the church in the 2nd century; for it contains nearly the whole of the famous work of Celsus (Λόγος ἀληθής) against Christianity. What makes Origen's answer so instructive is that it shows how close an affinity existed between Celsus and himself in their fundamental philosophical and theological presuppositions. The real state of the case is certainly unsuspected by Origen himself; but many of his opponent's arguments he is unable to meet except by a speculative reconstruction of the church doctrine in question. Origen's apologetic is most effective when he appeals to the spirit and power of Christianity. In details his argument is not free from sophistical subterfuges and superficial reasonings.

5. Of the dogmatic writings we possess only one in its integrity, and that only in the translation of Rufinus, Περὶ ἀρχῶν (On the Fundamental Doctrines). This work, which was composed before 228, is the first attempt at a dogmatic at once scientific and accommodated to the needs of the church. The material is drawn from Scripture, but in such a way that the propositions of the *regula fidei* are respected. This material is then formed into a system by all the resources of the intellect and of speculation. Origen thus solved, after his own fashion, a problem which his predecessor Clement had not even ventured to grapple with. The first three books treat of God, the world, the fall of spirits, anthropology and ethics. "Each of these three books really embraces, although not in a strictly comprehensive way, the whole scheme of the Christian view of the world, from different points of view, and with different contents." The fourth book explains the divinity of the Scriptures, and deduces rules for their interpretation. It ought properly to stand as first book at the beginning. The ten books of *Stromata* (in which Origen compared the teaching of the Christians with that of the philosophers, and corroborated all the Christian dogmas from Plato, Aristotle, Numenius and Cornutus) have perished, with the exception of fragments; so have the tractates on the resurrection and freewill.

6. Of practical theological works we have still the Προτρεπτικὸς εἰς μαρτύριον and the Σύνταγμα περὶ εὐχῆς. For a knowledge of Origen's Christian estimate of life and his relation to the faith of the church these two treatises are of great importance. The first was written during the persecution of Maximinus Thrax, and was dedicated to his friends Ambrosius and Protoctetus. The other also dates from the Caesarean period; it mentions many interesting details, and concludes with a fine exposition of the Lord's Prayer.

7. In his own lifetime Origen had to complain of falsifications of his works and forgeries under his name. Many pieces still in existence are wrongly ascribed to him; yet it is doubtful whether a single one of them was composed on purpose to deceive. The most noteworthy are the *Dialogues* of a certain Adamantius "de recta in Deum fide," which seem to have been erroneously attributed to Origen so early as the 4th century.

Outline of Origen's View of the Universe and of Life.—The system of Origen was formulated in opposition to the Greek philosophers on the one hand, and the Christian Gnostics on the other[1]. But the science of faith, as expounded by him, bears unmistakably the stamp both of Neo-Platonism and of Gnosticism. As a theologian, in fact, Origen is not merely an orthodox traditionalist and believing exegete, but a speculative philosopher of Neo-Platonic tendencies. He is, moreover, a judicious critic. The union of these four elements gives character to his theology, and in a certain degree to all subsequent theology. It is this combination which has determined the peculiar and varying relations in which theology and the faith of the church have stood to each other since the time of Origen. That relation depends on the predominance of one or other of the four factors embraced in his theology.

As an orthodox traditionalist Origen holds that Christianity is a practical and religious saving principle, that it has unfolded itself in an historical series of revealing facts, that the church has accurately embodied the substance of her faith in the *regula fidei,* and that simple faith is sufficient for the renewal and salvation of man. As a philosophical idealist, however, he transmutes the whole contents of the faith of the church into ideas which bear the mark of Neo-Platonism, and were accordingly recognized by the later Neo-Platonists as Hellenic[2]. In Origen, however, the mystic and ecstatic element is held in abeyance. The ethico-religious ideal is the sorrowless condition, the state of superiority to all evils, the state of order and of rest. In this condition man enters into likeness to God and blessedness; and it is reached through contemplative isolation and self-knowledge, which is divine wisdom.

As a means to the realization of this ideal, Origen introduces the whole ethics of Stoicism. But the link that connects him with churchly realism, as well as with the Neo-Platonic mysticism, is the conviction that complete and certain knowledge rests wholly on divine revelation, *i.e.,* on oracles. Consequently his theology is cosmological speculation and ethical reflection based on the sacred Scriptures. The Scriptures, however, are treated by Origen on the basis of a matured theory of inspiration in such a way that all their facts appear as the vehicles of ideas, and have their highest value only in this aspect. That is to say, his gnosis neutralizes all that is empirical and historical, if not always as to its actuality, at least absolutely in respect of its value. The most convincing proof of this is that Origen (1) takes the idea of the immutability of God as the regulating idea of his system, and (2) deprives the historical "Word made flesh" of all significance for the true Gnostic. To him Christ appears simply as the Logos who is with the Father from eternity, and works from all eternity, to whom alone the instructed Christian directs his thoughts, requiring nothing more than a perfect—*i.e.,* divine—teacher. In such propositions historical Christianity is stripped off as a mere husk. The objects of religious knowledge are beyond the plane of history, or rather belong to a supra-mundane history.

On this view contact with the faith of the church could only be maintained by distinguishing an exoteric and an esoteric form of Christianity. This distinction was already current in the catechetical school of Alexandria, but Origen gave it its boldest expression, and justified it on the ground of the incapacity of the Christian masses to grasp the deeper sense of Scripture, or unravel the difficulties of exegesis. On the other hand, in dealing with the problem of bringing his heterodox system into conformity with the *regula fidei* he evinced a high degree of technical skill. An external conformity was possible, inasmuch as speculation, proceeding from the higher to the lower, could keep by the stages of the *regula fidei,* which had been developed into a history of salvation. The system itself aims in principle at being thoroughly monistic; but, since matter, although created by God out of nothing, was regarded merely as the sphere in which souls are punished and purified, the system is pervaded by a strongly dualistic element. The immutability of God requires the eternity of the Logos and of the world. At this point Origen succeeded in avoiding the heretical Gnostic idea of God by assigning to the Godhead the attributes of goodness and righteousness. The pre-

[1]The opposition to the unitarians within the church must also be kept in mind.

[2]Porphyry says of Origen, κατὰ τὰς περὶ πραγμάτων καὶ τοῦ θείου δόξας Ἑλληνίζων (Euseb: *H.E.* vi. 19).

existence of souls is another inference from the immutability of God, although Origen also deduced it from the nature of the soul, which as a spiritual potency must be eternal. From this follows the necessity for the created spirit, after apostasy, error and sin, to return always to its origin in God.

The actual sinfulness of all men Origen was able to explain by the theological hypothesis of pre-existence and the premundane fall of each individual soul. He holds that freedom is the inalienable prerogative of the finite spirit; and this is the second point that distinguishes his theology from the heretical Gnosticism. The system unfolds itself like a drama, of which the successive stages are as follows: the transcendental fall, the creation of the material world, inaugurating the history of punishment and redemption, the clothing of fallen souls in flesh, the dominion of sin, evil and the demons on earth, the appearing of the Logos, His union with a pure human soul, His esoteric preaching of salvation, and His death in the flesh, then the imparting of the Spirit, and the ultimate restoration of all things. The doctrine of the restoration appeared necessary because the spirit, in spite of its inherent freedom, cannot lose its true nature, and because the final purposes of God cannot be foiled. The end, however, is only relative, for spirits are continually falling, and God remains through eternity the creator of the world. Moreover the end is not conceived as a transfiguration of the world, but as a liberation of the spirit from its unnatural union with the sensual.

The old Christian eschatology is set aside; no one has dealt such deadly blows to Chiliasm and Christian apocalypticism as Origen. It need hardly be said that he spiritualized the church doctrine of the resurrection of the flesh. But, while in all these doctrines he appears in the character of a Platonic philosopher, traces of rational criticism are not wanting. Where his fundamental conception admits of it, he tries to solve historical problems by historical methods. Even in the christology, where he is treating of the historical Christ, he entertains critical considerations; hence it is not altogether without reason that in after times he was suspected of "Ebionitic" views of the Person of Christ.

Although the theology of Origen exerted a considerable influence as a whole in the two following centuries, it certainly lost nothing by the circumstance that several important propositions were capable of being torn from their original setting and placed in new connections. It is in fact one of the peculiarities of this theology, which professed to be at once churchly and philosophical, that most of its formulae could be interpreted and appreciated *in utramque partem.* By arbitrary divisions and rearrangements the doctrinal statements of this "science of faith" could be made to serve the most diverse dogmatic tendencies. This is seen especially in the doctrine of the Logos. On the basis of his idea of God Origen was obliged to insist in the strongest manner on the personality, the eternity (eternal generation) and the essential divinity of the Logos[1]. On the other hand, when he turned to consider the origin of the Logos he did not hesitate to speak of Him as a *κτίσμα,* and to include Him amongst the rest of God's spiritual creatures. A *κτίσμα,* which is at the same time ὁμοούσιον τῷ Θεῷ, was no contradiction to him, simply because he held the immutability, the pure knowledge and the blessedness which constituted the divine nature to be communicable attributes.

In later times both the orthodox and the Arians appealed to his teaching, both with a certain plausibility; but the inference of Arius, that an imparted divinity must be divinity in the second degree, Origen did not draw. With respect to other doctrines also, such as those of the Holy Spirit and the incarnation of Christ, etc., Origen prepared the way for the later dogmas. The technical terms round which such bitter controversies raged in the 4th and 5th centuries are often found in Origen lying peacefully side by side. But this is just where his epoch-making importance lies, that all the later parties in the church learned from him. And this is true not only of the dogmatic parties; solitary monks and ambitious priests, hard-headed critical exegetes, allegorists, mystics, all found something congenial in his writings. The only man who tried to shake off the theological influence of Origen was Marcellus of Ancyra, who produced no lasting effect on theology.

The attacks on Origen, which had begun in his lifetime, did not cease for centuries, and only subsided during the time of the fierce Arian controversy. It was not so much the relation between *pistis* and *gnosis*—faith and knowledge—as defined by Origen that gave offence, but rather isolated propositions, such as his doctrines of the pre-existence of souls, of the soul and body of Christ, of the resurrection of the flesh, of the final restoration, and of the plurality of worlds. Even in the 3rd century Origen's view of the Trinity and of the Person of Christ was called in question, and that from various points of view. It was not till the 5th century, however, that objections of this kind became frequent. In the 4th century Pamphilus, Eusebius of Caesarea, Athanasius, the Cappadocians, Didymus and Rufinus were on the side of Origen against the attacks of Methodius and many others. But, when the zeal of Epiphanius was kindled against him, when Jerome, alarmed about his own reputation, and in defiance of his past attitude, turned against his once honoured teacher, and Theophilus, patriarch of Alexandria, found it prudent, for political reasons to condemn Origen—then his authority received a shock from which it never recovered.

There were, doubtless, in the 5th century church historians and theologians who still spoke of him with reverence, but such men became fewer and fewer. In the West Vincent of Lerins held up Origen as a warning example (*Commonit.* 23), showing how even the most learned and most eminent of church teachers might become a misleading light. In the East the exegetical school of Antioch had an aversion to Origen; the Alexandrians had utterly repudiated him. Nevertheless his writings were much read, especially in Palestine. The monophysite monks appealed to his authority, but could not prevent Justinian and the fifth oecumenical council at Constantinople (553) from anathematizing his teaching.

BIBLIOGRAPHY.—Next to the works of Origen (*see* Redepenning, "Des Hieronymus wiederaufgefundenes Verzeichnis der Schriften des Origens," in *Zeit. f. d. hist. Theol.* [1851], pp. 66 *seq.*) the most important sources are: Gregory Thaumat., *Panegyricus in Orig.;* Eusebius, *H.E.* vi.; Epiphanius, *Haer.* 64; the works of Methodius, the Cappadocians, Jerome (see *De vir. ill.* 54, 61) and Rufinus; Vincent. Lerin. *Commonit.* 23; Palladius, *Hist. Laus.* 147; Justinian, *Ep. ad Mennam* (Mansi, ix. p. 487 *seq.*); Photius, *Biblioth.* 118, etc. The best of the older editions is that of Delarue (1733–59, 4 vols. fol.; pub. by Migne in *Patrol. Gr.* vols. xi.–xvii.). A critical edition is being brought out by the Preussische Akademie der Wissenschaften; it is not yet completed. Amongst the older works on Origen those of Huetius (printed in Delarue, vol. iv.) are the best; but Tillemont, Fabricius, Walch (*Historie d. Ketzereien,* vii. pp. 362–760) and Schröckh also deserve to be mentioned. In recent times the doctrine of Origen has been expounded in the great works on church history by Baur, Dorner, Böhringer, Neander, Möller (*Geschichte der Kosmologie in der griechischen Kirche*) and Kahnis (*Die Lehre vom h. Geist,* vol. i.); compare with these the works on the history of philosophy by Ritter, Erdmann, Ueberweg and Zeller. Of monographs, the best and most complete is Redepenning, *Origenes, eine Darstellung seines Lebens und seiner Lehre* (2 vols., 1841, 1846). Compare Thomasius, *Orig.* (1837); Krüger, "Über das Verhältnis des Orig. zu Ammonius Sakkas," in the *Ztschr. f. hist. Theol.* (1843), i. p. 46 *seq.;* Fischer, *Comment. de Orig. theologia et cosmologia* (1846); Ramers, *Orig. Lehre von der Auferstehung des Fleisches* (1851); Knittel, "Orig. Lehre von der Menschwerdung," in the *Theol. Quartalschr.* (1872); Schultz, "Christologie des Orig.," in the *Jahrb. f. protest. Theol.* (1875); Mehlhorn, "Die Lehre von der menschlichen Freiheit nach Orig.," in *Zeitschr. f. Kirchengesch.* vol. ii. (1878); Freppel, *Origène,* vol. i., 2nd ed. (Paris, 1875). A full list of the later bibliography will be found in Bardenhewer's *Geschichte der altkirchen litteratur* (2nd ed. 2 vols., 1914) and de Faye *Origène,* vol. i. (1923). (A. HA.)

ORIGINAL PACKAGE, a legal term in America, meaning the package in which goods, intended for inter-State commerce, are actually transported wholesale. The term is used chiefly in determining the boundary between Federal and State jurisdiction in the regulation of commerce, and derives special significance by reason of the conflict between the powers of Congress to regulate commerce and the police legislation of the States with respect to commodities considered injurious to public health and morals.

By the Federal Constitution Congress is vested with the power "to regulate commerce with foreign nations and among the several States, and with the Indian tribes," and each State is forbidden, without the consent of Congress, to "lay any imposts or duties on imports or exports, except what may be absolutely necessary

[1] "Communis substantiae est filio cum patre; ἀπόρροια enim ὁμοούσιος videtur, i.e., unius substantiae cum illo corpore ex quo est ἀπόρροια."

for executing its inspection laws," and the basis of the law on the subject of "original package" was laid when, in 1827, Chief Justice Marshall interpreted these clauses in his decision of the case of *Brown* v. *Maryland* (12 Wheaton 419), which tested the constitutionality of an act of the legislature of Maryland requiring a licence from importers of foreign goods by bale or package and from persons selling the same by wholesale, bale, package, hogshead, barrel or tierce. After pronouncing such a licence to be in effect a tax, the chief justice observed that so long as the thing imported remained "the property of the importer, in his warehouse, in the original form or package in which it was imported," a tax upon it was too plainly a duty on imports to escape the prohibition of the Constitution.

Later decisions agree that the right to import commodities or to ship them from one State to another carries with it the right to sell them, and have established the boundary line between Federal and State control of both foreign imports and inter-State shipments at a sale in the original package (*Waring* v. *Mobile,* 8 Wall. 110) or at the breaking of the original package before sale for other purposes than inspection (*May* v. *New Orleans,* 178 U.S. 498). A State or a municipality may, however, tax while in their original packages any commodities which have been shipped in from another State, provided there be no discrimination against such commodities.

The term occasioned considerable confusion prior to the adoption of the 18th (prohibition) amendment to the Constitution in 1919. The Supreme Court in Jan. 1847, in the licence cases, upheld the constitutionality of Massachusetts, New Hampshire and Rhode Island laws requiring licences for the sale of intoxicating liquors, the liquor having been shipped in the inter-State commerce (5 Howard 504). The justices based their decisions on different opinions and did not even agree that the power of Congress to regulate inter-State commerce included the power to authorize a sale after shipment. The Supreme Court held in *Leisy* v. *Hardin,* in 1889, where a keg of beer sold in Iowa, a prohibition State, had been shipped from Illinois by order of an agent of an Illinois firm, that so long as it was sold in the original package, it remained a matter for Federal regulation only (135 U.S. 100). This overruled in part the doctrine in the licence cases. Congress passed in 1890 the Wilson Act, which provided that where intoxicants were shipped into a State or Territory, they were subject to the police laws of such State or Territory. Even with this act, however, a State was not permitted to interfere with an inter-State shipment of liquor direct to the consumer. The Webb Act, passed by Congress in 1913, did prohibit the shipment of liquor into any State in violation of its police laws.

What constitutes an original package was the principal question in the case of *Schollenberger* v. *Pennsylvania* (171 U.S. 1), the court deciding that the State of Pennsylvania could not prohibit the sale of oleomargarine by retail when it had been shipped from Rhode Island in packages containing only ten pounds each, and the original package doctrine has been sharply criticized because of the difficulty in determining what constitutes an original package, as well as because of the conflict between the doctrine and the police powers of the several States.

See J. B. Uhle, "The Law Governing an Original Package," in *The American Law Register,* vol. xxix. (Philadelphia, 1890); Shackelford Miller, "The Latest Phase of the Original Package Doctrine," and M. M. Townley, "What is the Original Package Doctrine?" both in *The American Law Review,* vol. xxxv. (St. Louis, 1901); also F. H. Cooke, *The Commerce Clause of the Federal Constitution* (1908).

ORIHUELA, a town and episcopal see of eastern Spain, in the province of Alicante; 13 m. N.E. of Murcia and about 15 m. from the Mediterranean Sea, on the Murcia-Elche railway. Pop. (1940) 11,983 (mun., 43,619). It is situated in an exceedingly fertile *huerta,* on both sides of the river Segura, which divides the city into two parts, Roig and San Augusto, and is spanned by two bridges. Orihuela was captured by the Moors in 713, and retaken by James I. of Aragon, for his father-in-law Alphonso of Castile, in 1265. It was sacked during the disturbances at the beginning of the reign of Charles V. (1520), and again in the War of Succession (1706). Local annals specially mention the plague of 1648, the flood of 1651 and the earthquake of 1829. The university of Orihuela, founded in 1568 by the archbishop of Valencia, was closed in 1835. The trade in fruit, cereals, oil and wine is considerable. There are also tanneries, dye and silk works, linen and woollen fabrics, leather and starch.

ORILLIA, a town and port of entry of Simcoe county, Ontario, situated 84 mi. N. of Toronto, on Lake Couchiching (which is on the Trent-Severn canal system) and on the Canadian National and Canadian Pacific railways. Pop. (1951) 12,110. It has an extensive trade in lumber and farm produce. It contains saw and grist mills, iron foundries, farm implement works, seagoing yacht works, woollen mills and other industries. It is a favourite summer resort, and at Couchiching beach there is a beautiful park with a monument commemorating Samuel de Champlain's sojourn in the area in 1618.

ORINOCO, a river and river system of northern South America. Its basin embraces about one-half of the eastern plains of Colombia and nearly all of Venezuela south and east of the Andes; it ranks third in area among the South American river basins. The main river is about 1,700 mi. long from its source in the Sierra Parima on the Venezuela-Brazil boundary to the Atlantic ocean and, except for a stretch of about 200 mi. between the mouths of the Guaviare and Meta rivers, where it forms a part of the Venezuela-Colombia boundary, it is in Venezuela. At about 150 mi. from its source it bifurcates into the Casiquiare canal to the Río Negro of the Amazon system, affording a through waterway to the Amazon basin. Three major rapids and numerous minor ones obstruct the upper river. At the mouth of the Apure the Orinoco is 2 mi. wide in the dry season and often 7 mi. wide in time of floods, and narrows to 800 ft. at the city of Ciudad Bolívar. Large steamers can navigate as far as the Cariben rapids, 700 mi. from the ocean and only 6 mi. from the mouth of the Meta. At the Cariben rapids the difference between high and low water averages 32 ft., while at the Angostura, at Ciudad Bolívar, the average rise is 50 ft. and has been known to reach 60.

The Orinoco enters the ocean by a delta of approximately 700 sq.mi. of islands and swamps covered with dense vegetation and so little above sea level that they are periodically flooded. The Boca Grande at the mouth of the Corosimi river (the southernmost channel of the delta) is the deepest outlet; but the Caño Macareo, one of the outlets of the Vagre river (the westernmost channel of the delta), is usually taken by steamers because it is the most direct navigable route to the Gulf of Paria.

Diego de Ordaz, whose expedition (1531–32) entered the Orinoco by the Boca de Navíos and, with much loss of life, ascended to the mouth of the Meta, was the first to explore any part of the river, although Christopher Columbus, while exploring the Gulf of Paria in 1498, noticed the freshness of its waters without investigating their source, and Alonso de Ojeda, following closely the track of Columbus in 1499, probably passed in sight of one or more of the mouths of the river. There have since been many expeditions and surveys.

Except for a few outliers which form isolated hills north of the lower river, the Orinoco is the dividing line between the *llanos* and the highlands of Venezuelan Guiana. The tributaries from the Guiana highlands are little known. They all have their sources in the divide which carries the Venezuela-Brazil boundary. The largest, the Ventuari, joins the Orinoco about 90 mi. above the mouth of the Guaviare. The Caura, the next large stream to the east, is much obstructed with falls and rapids, while the lower Caroni is more or less navigable for about 400 mi. The *llanos* are divided into a broad, well-watered western section and a narrower and much drier eastern section. North of the upper Guaviare and its tributaries the western section rises gently from an elevation of about 130 ft. at the mouth of the Apure to about 700 ft. at the border of the Andes. Its principal rivers have their sources in innumerable mountain torrents that rise in the eastern ranges of the Eastern Cordillera of Colombia. From the Guaviare north to 6° 30′ N. lat. these streams are fed so abundantly by the condensation of moisture from the northeast trade winds that they have headed far back toward the high savannas of the Eastern Cordillera. The most important tributaries of the Orinoco in

this section are the Apure, Arauca, Meta and Guaviare. The Apure is formed by the confluence of the Uribante and the Sarare. It follows a sluggish course eastward across the *llanos* for about 300 mi. to its junction with the Orinoco. It is in large part navigable for large craft but is obstructed by rapids about 100 mi. from its mouth. Its northern tributaries, which drain the eastern and southern slopes of the Venezuelan Andes, include the Suripá, the Santo Domingo, the Masparro, the Portuguesa and the Guarico. Of these the Portuguesa, which the cattle route from San Fernando to Puerto Cabello follows, and a few others are navigable for short distances.

The Arauca parallels the Apure on the south. The lateral channels between the two mingle in flood season.

The main stream of the Guaviare, southernmost of the great western tributaries of the Orinoco, is known as the Guayabero from its source to the mouth of the Ariari, a large tributary from the north-west. It marks in a general way the dividing line between the low savannas of the north and the higher and more varied topography of the south. The main stream and many of its tributaries after leaving the piedmont cut their way through four distinct zones: (1) a dissected sandstone plateau, the crests of which rise 1,500 ft. above the *llanos;* (2) a zone east of the escarpment of the plateau of sandstone remnants separated by clayey depressions; (3) a crystalline peneplain where the granites and gneisses are mostly covered with lateritic clays; and (4) a low plain on which stand isolated massifs of the dome-like form characteristic of crystalline mountains in wet tropical climates. The Ariari tributary is navigable for large barges for a considerable distance. About 300 m. of the Guayabero-Guaviare are said to be navigable but narrows and rapids which mark the passage of the river from one zone to another offer serious obstacles.

(R. R. P.)

ORIOLE, the name applied in Europe to the members of the family *Oriolidae.* The golden oriole (*Oriolus oriolus*) is an occasional spring visitor to the British Islands, but has rarely bred there. On the continent of Europe it is a well-known bird; its range in summer extends east to Irkutsk, while in winter it is found in Natal and Damaraland. In India it is replaced by an allied form, *O. kundoo,* the mango-bird, and both in Asia and Africa are several other species, some of which have a black head, or even a glowing crimson, instead of the ordinary yellow colouring, while others exhibit the dingy type of plumage seen in the female of the more normal form. Among these last are the species of the group, *Mimeta,* belonging to the Australian region, which mimic friar-birds (*see* A. R. Wallace, *Malay Archipelago;* HONEY-EATER). Another genus which has been referred to the *Oriolidae* is *Sphecotheres,* peculiar to the Australian region, and distinguishable by a bare space round the eye. Orioles are shy and restless birds, frequenting gardens and woods, and living on insects and fruit. The nest is pocket-shaped, of bark, grass, and fibres, and the eggs are white or salmon-coloured with dark spots. The name is applied in America to the *Icteridae* family.

ORION (or OARION), in Greek mythology, son of Hyrieus or Poseidon, a mighty hunter of great beauty and gigantic strength. He is also sometimes represented as sprung from the earth. He was beloved of Eos, the dawn-goddess, who carried him off to Delos; but Artemis slew him with her arrows (*Odyssey,* v. 121). According to other accounts which attribute Orion's death to Artemis, the goddess herself loved him and was deceived by the angry Apollo into shooting him by mistake; or he paid the penalty of offering violence to her, or of challenging her to a contest of quoit-throwing (Apollodorus i. 4; Horace, *Odes,* iii. 4, 71). In the lower world his shade is seen by Odysseus driving the wild beasts before him as he had done on earth (*Odyssey,* xi. 572). After his death he was changed into the constellation which is called by his name. It took the form of a warrior, wearing a girdle of three stars and a lion's skin, and carrying a club and a sword. When it rose early it was a sign of summer; when late, of winter and stormy weather; when it rose about midnight it heralded the season of vintage.

See Küentzle's article in Roscher's *Lexikon;* Preller-Robert, *Griechische Mythologie* (1894), pp. 448–454.

Orion is one of the most conspicuous constellations, containing many bright stars. Of these Betelgeuse is easily distinguished by its yellowish-red colour in contrast to all the other important stars of the constellation which are white B-type stars. Betelgeuse is an irregular variable sometimes above and sometimes below the first magnitude. It was the first star for which the apparent diameter was measured by Michelson's interferometer method (1920). Rigel at the opposite corner of the quadrilateral is rather brighter; and the third brightest star is Bellatrix. The Orion nebula can be seen with the naked eye just below the belt; faint extensions of it have been photographed filling practically the whole constellation. The multiple star θ Orionis is near the centre of the nebula. There is no doubt that the principal stars of the constellation form a single system, and are involved in the nebulosity whose luminescence is stimulated by their intense radiation rich in light of short wave-length. The distance of the nebula is estimated at 1,200 light years.

ORION and **ORUS,** the names of several Greek grammarians, frequently confused. The following are the most important. (1) Orion of Thebes in Egypt (5th century A.D.), the teacher of Proclus the neo-Platonist and of Eudocia, the wife of the younger Theodosius. He taught at Alexandria, Caesarea in Cappadocia and Byzantium. He was the author of a partly extant etymological Lexicon (ed. F. W. Sturz, 1820), largely used by the compilers of the *Etymologicum Magnum,* the *Etymologicum Gudianum* and other similar works; a collection of maxims in three books, addressed to Eudocia, also ascribed to him by Suidas, still exists in a Warsaw ms. (2) Orus of Miletus, who, according to Ritschl, flourished not later than the 2nd century A.D., and was a contemporary of Herodian and a little junior to Phrynichus. His chief works were treatises on orthography; on Atticisms; on the names of nations.

See F. Ritschl, *De Oro et Orione Commentatio* (1834); R. Reitzenstein, *Geschichte der griechischen Etymologika* (1897); and article "Orion" in Smith's *Dictionary of Greek and Roman Biography.*

ORISKANY (ō-rĭs'kạ-nĭ), a village of Oneida county, New York, U.S.A., about 7 mi. N.W. of Utica. Pop. (1950) 1,348. Oriskany is served by the New York Central railway. In a ravine, about 2 m. west of Oriskany, was fought on Aug. 6, 1777 the battle of Oriskany, an important minor engagement of the American Revolution. On Aug. 4, Gen. Nicholas Herkimer had gathered about 800 militiamen at Ft. Dayton (on the site of the present Herkimer, N.Y.) for the relief of Ft. Schuyler (*see* ROME, N.Y.) then besieged by British and Indians under Col. Barry St. Leger and Joseph Brant. On the 6th Gen. Herkimer's force, on its march to Ft. Schuyler, was ambushed by a force of British under Sir John Johnson and Indians under Joseph Brant in the ravine above mentioned. The rear portion of Herkimer's troops escaped from the trap, but were pursued by the Indians, and many of them were overtaken and killed. Between the remainder and the British and Indians there was a desperate hand-to-hand conflict, interrupted by a violent thunderstorm, with no quarter shown by either side. On hearing the firing near Ft. Schuyler (incidental to a sortie by Lt.-Col. Marinus Willett) the British withdrew, after about 200 Americans had been killed and as many more taken prisoners, the loss of the British in killed being about the same. Gen. Herkimer, though his leg had been broken by a shot at the beginning of the action, continued to direct the fighting on the American side, but died on Aug. 16, as a result of the clumsy amputation of his leg. The battle, though indecisive, had an important influence in preventing St. Leger from affecting a junction with Gen. Burgoyne. The battlefield is marked by a monument erected in 1884. The sesquicentennial of the battle was celebrated Aug. 6, 1927. The Oneida Historical society then presented to the state the battle monument and about 5 ac. of land for a state park.

See *Orderly Book of Sir John Johnson during the Oriskany Campaign* (Albany, 1882), with notes by W. L. Stone and J. W. De Peyster; *Publications* of the Oneida Historical Society, vol. i. (Utica, N.Y., 1877); and Phoebe S. Cowen, *The Herkimers and Schuylers* (Albany, 1903); T. G. Best, *A Soldier of Oriskany* (Boonville, N.Y., 1935); T. W. Clarke, *The Bloody Mohawk* (1940).

ORISSA, a state in northeastern India with an area of 59,869 sq.mi. and a population (1951 census) of 14,644,293. Cuttack

is the capital of the province; and Puri, with its temple of Jagannath, is world famous.

The Oriyas trace their traditions back to the ancient kingdom of Utkal. They have always been opposed to the breaking up of Oriya-speaking tracts for political reasons. At the time of the Mogul conquest the Orissa country was broken up, and race consciousness became less intense; but it was revived under the British regime, especially after the famine of 1866. Agitation for the unification of Oriya tracts began to receive official recognition in 1903 and was sustained by the Utkal Union conference.

In 1912 the area of modern Orissa was separated from Bengal and united with Bihar to form the province of Bihar and Orissa. The status of the Oriyas was much improved by this step, but they still continued their agitation for the formation of Orissa into a separate administrative unit on the basis of common language and race. In Jan. 1936 an order in council was issued by the British government constituting Orissa as a separate province. The new province was formed from: (1) the Orissa division of the former province of Bihar and Orissa; (2) areas transferred from the presidency of Madras including (*a*) the Ganjam Agency tracts, (*b*) parts of the Ganjam district and (*c*) parts of the Vizagapatam district; and (3) areas transferred from the Central Provinces including (*a*) the Khariar zamindari in the Raipur district and (*b*) the Padampur tract in the Bilaspur district. The province consists of six districts; viz., Sambalpur, Koraput, Ganjam, Cuttack, Puri and Balasore, the latter three constituting the delta of the Mahanadi, Brahmani and Baitarani rivers. In 1866 Orissa suffered from famine, followed by destructive floods, during which 1,000,000 persons are estimated to have perished, largely because of its isolation.

The danger of the recurrence of such a famine was averted by the Orissa canal system and the railway, as well as by the increased prosperity of the people. The occurrence of floods still occasionally causes distress. The beds of the deltaic rivers have been raised by deposits of silt and their outlets obstructed by sand bars until flood waters are not discharged by natural channels but are liable to burst the embankments and inundate the low-lying country on either side.

Orissa is still a backward region from an industrial and agricultural standpoint. There are no big factories but there are a number of cottage industries producing hand-loom products and metalwork. Production of jute and sugar cane as commercial crops is being steadily increased. There are forest resources of valuable timber. Mineral resources include iron ore of excellent quality, coal, limestone, manganese and mica. Orissa provides more than 60% of the iron ore extracted in India.

In 1948 the 39 minor states, formerly under the Chhattisgarh and Orissa agencies, were merged into the Central Provinces (Madhya Pradesh) and Orissa. In the following year, Mayurbhanj, the last surviving state in the area, was absorbed into Orissa.

BIBLIOGRAPHY.—R. D. Banerji, *History of Orissa*, 2 vol. (Calcutta, 1930–31); W. W. Hunter, *Orissa*, 2 vol. (London, 1872); *Report of the Orissa Committee*, 2 vol. (1932).

ORISTANO, a town and archiepiscopal see of Sardinia, Italy, 23 ft. above sea level, 3 mi. from the eastern shore of a gulf on the west coast, to which it gives its name and 59 mi. N.W. of Cagliari by rail. Pop. (1936) 9,454 (town), 14,662 (commune). The town has remains of the walls (1290) and two gates, the Porta Manna with a lofty square tower (Torre S. Cristoforo) and the Porta a Mare. The houses are made of sun-dried bricks. Two miles south of Oristano is the village of S. Giusta, with a beautiful Romanesque church of the Pisan period dedicated to this saint, containing several antique columns. The lagoons on the coast are full of fish, but are a cause of malaria. In the environs garden produce is grown; good wine (*vernaccia*) is made, as well as ordinary pottery. It is also a centre of the cattle trade. A mile south of the mouth of the river Tirso is the landing place for shipping. The large orange groves of Milis lie 13 mi. N. of Oristano at the base of Monte Ferru. The inhabitants of Milis manufacture reed baskets and mats, which they sell throughout Sardinia.

Oristano occupies the site of the Roman Othoca, the point at which the inland road and the coast road from Carales to Turris Libisonis bifurcated. The mediaeval town (1070) was the seat onward of the *giudici* (judges) of Arborea, one of the four divisions of the island. Almost the last of these judges was Eleonora (1347–1403); after her death Oristano became the seat of a marquisate, which was suppressed in 1478.

ORIZABA, a city in the Mexican state of Veracruz. Pop. (est. 1950) 65,000, 82 mi. W.S.W. of the port of Veracruz, 203 mi. S.E. of Mexico City, on main roads and the two railways connecting those points. Founded by Spaniards in the 16th century to guard these critical routes, Orizaba's strategic importance made it a centre of Mexican history, to which was added its economic development in a favourable habitat. It stands at 4,211 ft. in a fertile, well-watered and temperate valley of the Sierra Madre Oriental, over which towers the Pico de Orizaba, a famous snow-capped extinct volcano (18,548 ft.) 18 mi. N. Midway between the tropical lowlands on one side, the semiarid plateau on the other, Orizaba's sufficiency of water and temperate conditions make its district an important agricultural and industrial area. Crops include tobacco, maize, sugar, cereals and rum. The Rio Blanco furnishes hydroelectric power for numerous textile mills, tobacco factories and light industry, among which is one of the principal breweries of Mexico. The picturesque vegetation and pleasant climate make it a popular tourist place. Its citizens are famed for literature and business ability.

Though a garrison post of Aztecs, called by them *Ahuaializapan* ("pleasant waters"). Orizaba had a negligible native population. Its public edifices recall a long colonial past. It was chartered as a city in 1774 and was licensed under crown monopoly to produce tobacco. It was one of the first textile centres of Mexico.

(HD. C.)

ORIZABA, in Aztec, *Citlaltepetl,* "star mountain," an extinct or dormant volcano on the boundary between the Mexican states of Puebla and Veracruz and very nearly on the 19th parallel. It rises from the southeastern margin of the great Mexican plateau to an elevation of 18,314 ft., according to Scovell and Bunsen's measurements in 1891–92, or 18,250 and 18,209 ft. according to other authorities, and 18,701 (5,700 m.) by the Comisión Geográfica Exploradora. It is the highest peak in Mexico, probably third highest in North America. Its upper timber line is about 13,500 ft. above sea level, and Hans Gadow found patches of apparently permanent snow at an elevation of 14,400 ft. on its southeast side in 1902. The first ascent of Orizaba was made by Reynolds and Maynard in 1848. Its last eruptive period was 1545–66, and the volcano is now considered to be extinct.

ORJONIKIDZE (formerly VLADIKAVKAZ), a town of the Russian S.F.S.R., in the North Ossetian A.S.S.R., in 43° 3′ N., 44° 42′ E. Pop. (1939) 127,172. The former name Vladikavkaz meant "Key of the Caucasus"; the town stands on a plateau 2,345 ft. high on both sides of the Terek river, where the latter issues from the Darial gorge. Towering above the town is the famous Kasbek peak. A small fort was established there in 1784, but the expansion of the town dates from the completion of the great Georgian military road southward through the gorge to Tiflis, which was begun in 1811 and opened in 1864. Later a railway link was made through Beslan to the Rostov-Baku line to the north. The great gorge has much historic importance for the region; through it came Persian armies and, later, Timur and his Mongol hordes, and its military road brought about the pacification of the warring Caucasian frontier tribes and gave Russia her foothold in the Caucasus. The town was renamed Orjonikidze after the famous soviet leader.

ORKHON INSCRIPTIONS, ancient Turkish inscriptions of the 8th century A.D., discovered near the river Orkhon to the south of Lake Baikal in 1889. They are written in an alphabet derived from an Aramaic source and recount the history of the northern branch of Turks or Tu-kiue of Chinese historians. *See* TURKS.

ORKNEY, EARL OF, a Scottish title held at different periods by various families, including its present possessors the Fitzmaurices. The Orkney Islands (*q.v.*) were ruled by jarls or earls under the supremacy of the kings of Norway from very early times to about 1360, many of these jarls being also earls of Caith-

ness under the supremacy of the Scottish kings. Perhaps the most prominent of them were a certain Paul (d. 1099) who assisted the Norwegian king, Harald III. Haardraada, when he invaded England in 1066; and his grandson Paul the Silent, who built, at least in part, the cathedral of St. Magnus at Kirkwall. They were related to the royal families of Scotland and Norway.

In its more modern sense the earldom dates from about 1380, and the first family to hold it was that of Sinclair, Sir Henry Sinclair (d. *c.* 1400) of Roslin, near Edinburgh, being recognized as earl by the king of Norway. He ruled the islands almost like a king, and employed in his service the Venetian travellers Nicolo and Antonio Zeno. His son Henry (d. 1418) was admiral of Scotland and was taken prisoner by the English in 1406, together with Prince James, afterwards King James I.; his grandson William, the 3rd earl (*c.* 1404–80), was chancellor of Scotland and took some part in public affairs. In 1455 William was created earl of Caithness, and in 1470 he resigned his earldom of Orkney to James III. of Scotland, who had just acquired the sovereignty of these islands through his marriage with Margaret, daughter of Christian I., king of Denmark and Norway. In 1567 Queen Mary's lover, James Hepburn, earl of Bothwell, was created duke of Orkney, and in 1581 her half-brother Robert Stewart (d. 1592), an illegitimate son of James V., was made earl of Orkney. Robert, who was abbot of Holyrood, joined the party of the reformers and was afterwards one of the principal enemies of the regent Morton. His son Patrick acted in a very arbitrary manner in the Orkneys, where he set the royal authority at defiance; in 1609 he was seized and imprisoned, and, after his bastard son Robert had suffered death for heading a rebellion, he himself was executed in Feb. 1614, when his honours and estates were forfeited.

In 1696 Lord George Hamilton was created earl of Orkney. He married Elizabeth Villiers, and was succeeded by his daughter Anne (d. 1756), the wife of William O'Brien, 4th earl of Inchiquin. Anne's daughter Mary (*c.* 1721–91) and her granddaughter Mary (1755–1831) were both countesses in their own right, the younger Mary married Thomas Fitzmaurice (1742–93), son of John Petty, earl of Shelburne, and was succeeded in the title by her grandson, Thomas John Hamilton Fitzmaurice (1803–77), whose descendants still hold the earldom.

See *Records of the Earls of Orkney, 1299–1664*, ed. by J. S. Clouston (1914).

ORKNEY ISLANDS, group forming a county off the north coast of Scotland. They are separated from the mainland by the Pentland firth, which is 6¼ mi. wide between Brough Ness in the island of South Ronaldshay and Duncansbay head in Caithness-shire. The group consists of 67 islands (excluding rocky islets), of which 28 were inhabited in 1931, four of them only by lighthouse attendants. They measure 50 mi. from northeast to southwest, and 29 mi. from east to west, and cover 376.3 sq.mi. Excepting on the west coasts of the larger islands, which present rugged cliff scenery, the group lies somewhat low and is of bleak aspect, owing to the absence of trees. The islands are built up wholly of Old Red Sandstone. The Old Man of Hoy is a fine stack of rock standing detached from the north-west cliffs. The only other islands containing heights of any importance are Pomona, with Ward hill (880 ft.), and Wideford (740 ft.) and Rousay. Erratics of distant origin (*e.g.*, from Moray firth) give evidence of glacial action. Nearly all of the islands possess lakes, the largest being Loch Harray and Loch Stenness in Pomona. The rivers are merely streams. Excepting on the west fronts of Pomona, Hoy and Rousay, the coast-line of the islands is deeply indented, and the islands themselves are divided from each other by straits, generally called *sounds* or *firths,* though off the north-east of Hoy is *Bring Deeps,* south of Pomona is Scapa *Flow* and to the south-west of Eday is the *Fall* of Warness. The topographical names are Norse, and the common terminal of the names of the islands, *a* or *ay*, is the Norse *ey*, meaning "island." The islets are usually called *holms* and the isolated rocks *skerries.* The tidal currents, or *roost* (as some of them are called locally, from the Icelandic), off many of the isles run very fast and whirlpools are frequent.

History.—The Orkneys were the *Orcades* of classical writers, and the word is probably derived from the Norse *Orkn,* seal, and *ey,* island. Evidences of prehistoric occupation include numerous weems or underground houses, chambered mounds, barrows or burial mounds, *brochs* or round towers, and stone circles and standing stones. Three of the most famous are the corbelled tomb at Maeshowe, and the circles of standing stones at Brogar and Stennis with an early village discovered in 1928. If, as seems likely, the Dalriadic Scots towards the beginning of the 6th century established a footing in the islands, their success was short-lived, and the native inhabitants regained power and kept it until dispossessed by the Norsemen in the 9th century. The Celtic missionaries, companions of St. Columba, followed about 565. As the Norse pirates made raids on Norway from the islands, as well as on Scotland, Harold Haarfager ("Fair Hair") subdued the rovers in 875 and added the Orkneys and Shetlands to Norway. They remained under the rule of Norse earls until 1231, when the line of the earls became extinct. In that year the earldom of Caithness was granted to Magnus, second son of the earl of Angus, whom the king of Norway apparently confirmed in the title. In 1468 the Orkneys and Shetlands were pledged by Christian I. of Denmark for the payment of the dowry of his daughter Margaret, betrothed to James III. of Scotland, and as the money was never paid, their connection with the crown of Scotland has been perpetual. In 1471 William, earl of Orkney, exchanged his earldom for lands in Fife, and the islands were annexed to the Scottish crown. In 1581 Lord Robert Stewart, natural son of James V., was created earl of Orkney, but in 1615 the earldom was again annexed to the crown. The islands were the *rendezvous* of Montrose's expedition in 1650 which culminated in his imprisonment and death. In 1707 the islands were granted to the earl of Morton in mortgage, but in 1766 his estates were sold to Sir Lawrence Dundas, ancestor of the marquesses of Zetland.

In early times both the archbishop of Hamburg and the archbishop of York disputed with the Norwegians ecclesiastical jurisdiction over the Orkneys; but ultimately the Norwegian bishops, the first of whom was William the Old, consecrated in 1102, continued the canonical succession. The see, left vacant on several occasions, was finally abolished in 1697, although many of the clergy refused to conform. The Norse tongue, at last extinguished by the constant influx of settlers from Scotland, lingered until the end of the 18th century. When the islands were given as security for the princess's dowry, there seems reason to believe that it was intended to redeem the pledge, because it was then stipulated that the Norse system of government and the law of St. Olaf should continue to be observed in Orkney and Shetland. Thus the *udal* succession and mode of land tenure (or, that is, absolute freehold as distinguished from feudal tenure) still obtain to some extent, and the remaining *udallers* hold their lands and pass them on without written title.

Agriculture and Industries.—The soil generally is a sandy loam or a strong but friable clay, and very fertile. About 45% of the total area was under cultivation in 1938 and farming is now up to the general Scottish standard. The crofters' houses have been rebuilt of stone and lime, and are superior to those in most parts of the Highlands. Of the 3,203 holdings in 1938, about 55% were between 5 and 30 ac., the average being 34 ac. The grain crops are oats and barley, while the favoured root crops are turnips and potatoes. Cattle and sheep are reared, some pigs are kept, and the horses—as a rule hardy, active and small—are numerous. The woollen, linen, straw-plaiting and kelp industries have all successively failed, though the last named has been revived. Sandstone is quarried on several islands, and distilleries are found in Pomona. About half the population is engaged in agriculture. Apart from this, the principal industry is fishing. For several centuries the Dutch practically monopolized the herring fishery, but when their supremacy was destroyed by the salt duty, the fisheries were almost totally neglected. The industry, however, is now of considerable importance, particularly the herring fishery, followed by the cod, ling and lobster fisheries. There is a regular communication by steamer between Stromness and Kirkwall, and Thurso, Wick, Aberdeen and Leith, and also between Kirkwall and Ler-

wick and other points of the Shetlands.

Population and Administration.—The county population was 21,258 in 1951. In 1951 there were 51 persons who spoke Gaelic and English but none who spoke Gaelic only. Orkney unites with Shetland to send one member to parliament. Kirkwall, the county town, is the only royal burgh. Kirkwall (pop. 4,348 in 1951) and Stromness (1,503) are the only small burghs. Orkney forms a sheriffdom with Shetland and Caithness.

The Inhabited Islands.—From south to north, the islands (1931 population in brackets) include Sule Skerry (lighthouse, 6), Pentland Skerries (lighthouse, 5), Swona (6), South Ronaldshay (1,312), Hoy (955). On Hoxa head is a *broch*, or round tower, and the island contains examples of Picts' houses and standing stones. The famous Dwarfie stone, an enormous block of sandstone with rooms hollowed out in it, lies in a valley near Ward hill. Flotta (282), east of Hoy, was the home for a long time of the Scandinavian compiler of the *Codex Flotticensis*, which furnished Thormodr Torfaeus (1636–1719), the Icelandic antiquary, with many of the facts for his *History of Norway*. Pharay (40) also lies east of Hoy. Burray (379) is famous for the *broch* from which the island takes its name (Borgarey, Norse, "island of the broch"). The tower stands on the northwestern shore, is 15 ft. high, has walls from 15 to 20 ft. thick, built of layers of flat stones without cement or mortar, and an interior diameter of 40 feet. Between Hoy and Pomona are Hunda (3 in 1921, nil in 1931), Cava (14) and Graemsay (114). It was around Cava that the 70 vessels of the German navy were scuttled in 1919; 32 were raised between 1924 and 1931, and salvage operations were renewed in 1934. The isle, surrounded by shoals, has two lighthouses. The cliffs of Copinsay (25) are a favourite haunt of sea-birds.

Pomona (*q.v.*) is the principal island and is known as Mainland. Shapinsay (576) was the birthplace of William Irving, father of Washington Irving. It possesses several examples of Pictish and Scandinavian antiquities and Balfour Castle, built in 1848. Gairsay (5) was the home of Sweyn Asleifson, the rover. At Lamb head is a *broch* and Pictish pier, and on Odin bay is a round pit in the rocks called the Vat of Kirbuster. Papa Stronsay (18) commemorates the Celtic *papae*, or missionaries, who preached before the arrival of the Northmen. The adjacent Wyre or Veira has a population of 44; Egilsay (85) is the island on which St. Magnus was murdered by his cousin Hacco in 1115. It derives its name (*ecclesia*) from the little church of St. Magnus, now in ruins. The round tower resembles similar ones found beside Irish churches of the 7th and 8th centuries and has walls 3 ft. thick. Eday (430) contains weems, mounds and standing stones. Carrick village was named after the earl of Carrick. It was off this island that John Gow, the pirate, was taken in 1725. Stronsay (953) and Rousay (468) are other large islands.

Sanday (1,160), one of the largest northern islands, has an area of 19 sq.mi. It produces potatoes and grain and has harbours at Otterswick and Kettletoft. The antiquities include a *broch* in Elsness. Pharay (28). Westray (1,269) has a harbour at Pier-o'-wall. Noltland castle was proposed as the refuge of Queen Mary after her flight from Loch Leven. It was at one time the property of Sir Gilbert Balfour, the master of Queen Mary's household. At the westerly point, there is the Stack of Noup. Gentleman's Cave afforded shelter to five followers of Prince Charles Edward during the winter of 1745–46.

Papa Westray (237) and North Ronaldshay (298) are the most northerly islands. The latter is reached only from Sanday over a dangerous firth 2½ mi. wide. The monumental stone with Ogham inscription, discovered in the *broch* of Burrian, must date from early Christian missionary times.

ORLANDO, VITTORIO EMANUELE (1860–1952), Italian politician and jurist, was born at Palermo on May 19, 1860. Becoming a barrister and a law professor, he was first elected deputy for Partinico in Sicily in 1897. He was minister of education in the Giolitti cabinet of 1903–05, and of justice in the Giolitti cabinet of 1907–09, and again under Salandra in November 1914. Although a Giolittian at heart, he was in favour of Italian intervention in World War I. On the resignation of the Salandra cabinet in June 1916 he remained in office under Boselli as minister of the interior, and when the latter resigned Orlando was entrusted with the formation of a new cabinet. After the Armistice he went to Paris as president of the Italian peace delegation. When President Wilson launched his appeal on Fiume to the Italian people over the heads of their delegates, he returned to Rome, where he was triumphantly received, but after his return to Paris without the guarantees he was supposed to have secured, and without obtaining any satisfactory solution of the Adriatic problem, the chamber voted against him and he resigned on June 19, 1919. On Dec. 2, 1919, he was elected president of the chamber. He at first supported fascism and Mussolini, but after the Matteotti affair he withdrew his support, without, however, abandoning the chamber. At the municipal elections of Palermo in Aug. 1925 he mobilized all his adherents in favour of the antifascist list. He resigned from parliament in protest of the fraudulent fascist victory. After the fall of fascism, he was a member of the constituent assembly and later became a member of the Italian senate. In 1947 he resigned his seat in the constituent assembly. He died in Rome on Dec. 1, 1952.

See L. Hautecoeur, *L'Italie sous le ministère Orlando, 1917–19* (1919); R. Lansing, *The Big Four* (1922).

ORLANDO, a city of Florida, U.S., the county seat of Orange county and largest inland city of the state. It is on federal highways 17 and 441 and is served by the Atlantic Coast Line and the Seaboard Air Line railways. The population in 1950 was 52,367 by federal census.

Orlando is located in the heart of the rich citrus-growing area. Its lakes, parks and largemouth bass fishing attract many visitors. Orlando, originally called Jernigan, was founded in 1843 and incorporated in 1875.

ORLEANAIS, a former French province, of which Orléans was the regional capital; its limits changed from period to period. In ancient Gaul, Cenabum (Orléans) and Carnutum (Chartres) were the chief towns in the *civitas* of the Carnutes, which, in the 4th century, the Romans divided into two parts, Civitas Carnutum and Civitas Aurelianorum, the latter corresponding roughly to the later diocese of Orléans and to the 9th-century county of Orléans. This is Orléanais *stricto sensu*. But a larger territory, spreading over Blésois, Vendômois, Dunois, Beauce and Gâtinais, was sometimes administered from Orléans and lay under its economic and cultural influence; for example, in the 17th and 18th centuries, the above-mentioned territories were included in the *gouvernement* and in the *généralité* of Orléans, which corresponded to the modern departments of Loiret, Loir-et-Cher and Eure-et-Loir.

From the time of Robert the Strong, duke of the country between the Seine and the Loire (861–866), Orléanais was a seat of power of the Robertian family. Hugh Capet was count of Orléans as well as of Etampes and Paris; and under the early Capetians Orléans competed with Paris for the rank of capital. Under the Valois, however, Orléanais became an appanage (*see* ORLEANS, DUKES OF).

See also R. Crozet, *Histoire de l'Orléanais* (Paris, 1936). (F. CT.)

ORLEANISTS, a French political party which arose out of the Revolution. It took its name from the Orléans branch of the house of Bourbon, the descendants of Philippe, duke of Orléans, younger brother of Louis XIV, who were its chiefs. Its aim was to reconcile the monarchical principle with the "rights of man," as proclaimed by the constituent assembly in 1789. The Orléans princes were traditionally marked out as the leaders in such a policy. Enormously rich, within measurable distance of the succession to the throne, but cut off by the jealousy of the crown from all share in public affairs, they had long been the centres of opposition to the encroachment of the royal power. Louis, duke of Orléans, had headed the protest of the princes against the policy of René Maupeou in suppressing the *parlement* of Paris; his son later earned the style of Philippe Egalité by adopting—with ulterior objects—extreme revolutionary views (*see* ORLEANS, LOUIS PHILIPPE JOSEPH); and Egalité's son Louis Philippe (afterward king of the French) fought, as duc de Chartres, at Jemappes, under the republican tricolour. The generation of Orléanists, the immediate supporters of Philippe Egalité, were swamped in the turmoil of the Revolution. But they came naturally to the front when another revolution

overthrew the restored legitimate monarchy of Louis XVIII and Charles X. During the Restoration, 1815–30, everything tended to identify the Liberals with the Orléanists. It is true that Louis XVIII had been induced to grant (*octroyer*) a constitutional charter; but he and his successor claimed to rule by divine right and to confer liberties upon their subjects of their own will. The difference between the Legitimists and the Orléanists was thus fundamental. So was that between the Orléanists and the Bonapartists; for the former aimed at securing political liberty, in addition to equality before the law and in social life, while the latter aimed at subjection to a military despotism.

The revolution of 1830 brought the Orléanists into power, and they marked the profound change made in the character of the government by styling Louis Philippe not "king of France and Navarre by the grace of God," but "king of the French by the grace of God and the will of the people." The Orléanists were led by men eminent in letters and in practical affairs—François Guizot, Louis Thiers, the Broglies, the banker Jacques Laffitte and many others—and the 18 years of their rule were, on the whole, profitable to France. That they ended in another "general overturn" in 1848 was mainly because the Orléanist conception of what was meant by the word "people" led the government to offend the deeply rooted love of the French for equality. On the model of the English constitution they instituted a *pays légal* of about 250,000 voters by whom all the rest of the country was to be "virtually represented." But the nation outside of the *pays légal* soon discovered that it was being governed by a privileged class, less offensive perhaps, but also less brilliant, than the aristocracy of the old monarchy.

The revolution of 1848 swept the Orléanists from power forever. They continued indeed throughout the second republic and the Second Empire (1848–70) to enjoy a marked prestige, because of the wealth and capacity of some of their members, their influence in the French academy and the ability of their organs in the press. But their weakness was demonstrated when the Second Empire was swept away by the German War of 1870–71. The country, in its disgust at the Bonapartists and its fear of the Republicans, chose a great many royalists to represent it in the assembly which met in Bordeaux on Feb. 12, 1872. In this body the Orléanists again exercised a kind of leadership by virtue of individual capacity, but they were counterbalanced by the Legitimists. They defeated Thiers on May 24, 1873, as punishment for his dexterous imposition of the republic on the unwilling majority of the assembly. Their real occupation was to endeavour to bring about a fusion between themselves and the Legitimists. As far back as 1850 Guizot had proposed, or had thought of proposing, such a fusion, but it was on the condition that the comte de Chambord would resign his divine pretentions. The fusion arranged in 1873 was on quite another footing. After much exchange of notes and many agitated conferences, the comte de Paris, the representative of the Orléanists, sought an interview with the comte de Chambord at Frohsdorff, and obtained it by giving a written engagement that he came not only to pay his respects to the head of his house, but also to "accept his principle." Orléanists have declared that the engagement was given with mental reservations; but the country believed that the liberal royalists had been absorbed in the divine-right royalists, and returned republicans at by-elections till it transformed the assembly. The Orléanist princes had still a part to play, particularly when the death of the comte de Chambord in 1883 left them heads of the house of France, but the Orléanist party ceased to exist as an independent political organization.

BIBLIOGRAPHY.—The Orléanists are necessarily more or less dealt with in all histories of France since 1789, and in most political memoirs, but their principles can be learned and their fortunes followed from the following: A. Sorel, *L'Europe et la révolution française* (1885–1904); F. Guizot, *Histoire parlementaire de la France* (1819–48) and *Mémoires pour servir à l'histoire de mon temps* (1858–67); P. de la Gorce, *Histoire du second empire* (1894–1904); and G. Hanotaux, *Histoire de la fondation de la 3ème République* (1925). For the attitude of the Orléans princes towards the crown under the old regime, see Amédée Britsch, *La Jeunesse de Philippe Égalité* (1927).

ORLEANS, DUKES OF. The title of duke of Orléans was first created by King Philip VI in favour of his son Philip, who died without legitimate issue in 1375. The second duke of Orléans, created in 1392, was Louis, a younger son of Charles V, whose heir was his son the poet Charles of Orléans. Charles's son Louis, the succeeding duke, became king of France as Louis XII in 1498, when the duchy of Orléans was united with the royal domain. In 1626 Louis XIII created his brother Jean Baptiste Gaston (d. 1660) duke of Orléans, and the title was revived in 1661 by Louis XIV in favour of his brother Philip. Descendants of this duke have retained the title until the present day, one of them becoming king of France as Louis Philippe in 1830. Two distinguished families are descended from the first house of Orléans: the counts of Angoulême, who were descended from John, a son of Duke Louis I, and who furnished France with a king in the person of Francis I; and the counts and dukes of Longueville, whose founder was John, count of Dunois, the bastard of Orléans, a natural son of the same duke. In addition to the dukes of Orléans the most important members of this family are: Anne Marie Louise, duchess of Montpensier; Francis, prince of Joinville; Louis Philippe Albert, count of Paris; and the traveller Prince Henry of Orléans. (*See* BOURBON, table.)

ORLEANS, CHARLES, DUKE OF (1391–1465), commonly called Charles d'Orléans, French poet, was the eldest son of Louis, duke of Orléans (brother of Charles VI of France), and of Valentina Visconti, daughter of Gian Galeazzo, duke of Milan. He was born on May 26, 1391. He married (June 29, 1406), Isabella, his cousin, widow of Richard II of England. She died three years later. He was already duke of Orléans, for Louis had been assassinated by the Burgundians two years before (1407). He was now the most important person in France, except for the dukes of Burgundy and Brittany, the king being a cipher. He was, however, only nominally one of the leaders of the civil war, the real guidance of his party resting with Bernard VII, the great count of Armagnac, whose daughter Bonne he married, or at least formally espoused, in 1410. Five years of confused negotiations, plots and fightings passed before the English invasion and the battle of Agincourt, where Charles was joint commander in chief. He was taken prisoner and carried to England, where he remained for a full quarter of a century. He hunted and hawked and enjoyed society amply, though the very dignities which secured him these privileges made his ransom great and his release difficult to arrange. Above all, he had leisure, however, for literary work which consisted of short poems in the artificial metres then fashionable in France. Besides these a number of English poems have been attributed to him, but without certainty. For practical purposes his work consists of some hundreds of short French poems, a few in various metres, but the majority either ballades or rondels. Charles d'Orléans is the last representative of the poetry of the middle ages, in which the form was almost everything, and the personality of the poet, save in rare instances, nothing. He has the urbanity of the 18th century without its vicious and prosaic frivolity. His best-known rondels—those on spring, on the harbingers of summer, and others—rank second to nothing of their kind.

The agreement for his release from captivity was concluded on July 2, 1440. He was actually released on Nov. 3, and then married Mary of Cleves, who brought him a considerable dowry to assist the payment of his ransom. After his return to France he maintained at Blois a miniature court, at which the best-known French men of letters at the time—François Villon, Olivier de la Marche, Georges Chastellain, Jean Meschinot and others—were residents or visitors or correspondents. His son, afterward Louis XII, was born in 1462. Charles died on Jan. 4, 1465, at Amboise.

The best edition of Charles d'Orléans's poems, with a brief but sufficient account of his life, is that of C. d'Héricault in the *Nouvelle collection Jannet* (Paris, 1874). For the English poems *see* the edition by Watson Taylor for the Roxburghe Club (1827). *See* also C. Bruneau, *Charles d'Orléans et la poésie aristocratique* (Lyons, 1924).

ORLEANS, FERDINAND PHILIP LOUIS CHARLES HENRY, DUKE OF (1810–1842), born at Palermo on Sept. 3, 1810, was the son of Louis Philippe, duke of Orléans, afterward king of France, and Marie Amélie, princess of the Two Sicilies. Under the Restoration he bore the title of duke of Chartres, and studied classics in Paris at the Collège Henri IV. At the outbreak of the revolution which in 1830 set his father on the throne, he was colonel of a regiment of Hussars. He assumed the title of duke of Orléans, and was sent by the king to put down the riots at Lyons (1831), and then to the siege of Antwerp (1832). He was appointed lieutenant general, and made several campaigns in Algeria (1835, 1839, 1840). On his return to France he organized the *chasseurs d'Orléans*. He died after an accident at Neuilly, near Paris, on July 13, 1842.

The duke of Orléans had married (May 30, 1837) Helène Louise Elisabeth of Mecklenburg-Schwerin, and had by her two sons, the count of Paris and the duke of Chartres. On Feb. 24, 1848, after the abdication of Louis Philippe, the duchess of Orléans went to the chamber of deputies in the Palais Bourbon in the hope of having her eldest son proclaimed and of obtaining the regency; the attitude of the populace forced her to take refuge in England, and she died at Richmond, Eng., on May 18, 1858.

ORLEANS, HENRI, PRINCE OF (1867–1901), eldest son of Robert, duke of Chartres, was born at Ham, near Richmond, Surrey, Eng., on Oct. 16, 1867. In 1889, at the instance of his father, he undertook, in company with P. G. Bonvalot, a journey through Siberia to Siam. They crossed the mountain range of Tibet, and the fruits of their observations, submitted to the

Geographical Society of Paris and later incorporated in *De Paris au Tonkin à travers le Tibet inconnu* (1892), brought them conjointly the gold medal of that society. In 1892 the prince made a short journey in East Africa, and shortly afterward visited Madagascar, proceeding thence to Tongking. From there he set out for Assam, and found the sources of the Irrawaddy, which secured the medal of the Geographical Society of Paris and the cross of the Legion of Honour. In 1897 he revisited Abyssinia, and political differences arising from this trip led to a duel with the comte de Turin, in which both combatants were wounded. While on a trip to Assam he died at Saigon on Aug. 9, 1901.

ORLEANS, HENRIETTA, DUCHESS OF (1644–1670), third daughter of the English king Charles I (*q.v.*) and his queen, Henrietta Maria (*q.v.*), was born during the Civil War at Exeter on June 16, 1644. A few days after her birth her mother left England, and she lived at Exeter under the care of Lady Dalkeith (afterward countess of Morton) until the surrender of the city to the parliamentarians, when she was taken to Oatlands in Surrey. In July 1646 she rejoined her mother in Paris, where her girlhood was spent and where she was educated as a Roman Catholic. Henrietta was mentioned as a possible bride for Louis XIV (*q.v.*), but she was betrothed to his only brother, Philip. After the restoration of her brother Charles II (*q.v.*), she returned to England with her mother, but a few months later she was again in Paris, where she was married to Philip, now duke of Orléans, on March 30, 1661. The duchess was popular at the court of Louis XIV and was on good terms with the "grand monarch," but she was soon estranged from her husband, and her conduct was imprudent. In 1670, at the instigation of Louis, but without Philip's consent, she visited England and obtained the signature of Charles II's ministers to the treaty of Dover (*q.v.*). Shortly after returning to France, Henrietta died at St. Cloud on June 30, 1670, and it was asserted that she had been poisoned by order of her husband. She left two daughters, Maria Louisa, later wife of Charles II (*q.v.*) of Spain, and Anne, later wife of Victor Amadeus II (*q.v.*) of Savoy, king of Sardinia (*see* SAVOY, HOUSE OF).

ORLEANS, JEAN BAPTISTE GASTON, DUKE OF (1608–1660), third son of the French king Henry IV and his wife Marie de Medici, was born at Fontainebleau on April 25, 1608. Known at first as the duke of Anjou, he was created duke of Orléans in 1626, and was nominally in command of the army which besieged La Rochelle in 1628. On several occasions he was obliged to leave France for conspiring against the government of his mother, of Cardinal Richelieu and of Louis XIII. Orléans stirred up Cinq-Mars to attempt Richelieu's murder, and then deserted him. In 1643, on the death of Louis XIII, Gaston became lieutenant general of the kingdom, and fought against Spain on the northern frontiers of France; but during the wars of the Fronde he passed from one party to the other. Exiled by Jules Mazarin in 1652 he remained in Blois until his death on Feb. 2, 1660. Gaston's first wife was Marie (d. 1627), daughter and heiress of Henri de Bourbon, duc de Montpensier (d. 1608), and his second wife, Marguerite (d. 1672), sister of Charles III, duke of Lorraine. By Marie he left a daughter, Anne Marie, duchesse de Montpensier (*q.v.*); and by Marguerite he left three daughters, Marguerite Louise (1645–1721), wife of Cosimo III, grand duke of Tuscany; Elizabeth (1646–96), wife of Louis Joseph, duke of Guise; and Françoise Madeleine (1648–64), wife of Charles Emmanuel II, duke of Savoy.

ORLEANS, LOUIS, DUKE OF (1372–1407), younger son of the French king Charles V, was born on March 13, 1372. Having been made count of Valois and of Beaumont-sur-Oise and then duke of Touraine, he received the duchy of Orléans from his brother, Charles VI, in 1392. In 1388 he played an important part in persuading the king to get rid of the tutelage of his three uncles, after which he in fact ruled France, with the help of the *Marmousets* (the former ministers of Charles V). But when Charles VI became insane in 1392 the *Marmousets* were dismissed, and the king's uncles became influential in the government again. Despite an agreement whereby foreign policy was to be controlled by Louis and general policy by Philip (the Bold), duke of Burgundy, a quarrel soon developed between Louis and Philip and became the dominating factor in French politics. Louis was attractive and intelligent; but his private life was dissolute, and he liked extravagant life at court. He thought of politics as a game, cynically. On Jan. 27, 1389, he had married Valentina (d. 1408), daughter of Gian Galeazzo Visconti, duke of Milan, who brought him the county of Asti (this marriage later furnished Louis XII and Francis I with the pretext for their claims on Milan); and soon Louis's foreign policy was involved in Italian affairs. In 1390 and 1393 there were plans of a great expedition to Italy, where the schismatical pope Clement VII offered Louis a kingdom of Adria; and in 1396 Louis arranged the cession of Genoa to France. Meanwhile, he had bought the duchy of Luxembourg. Hostile to England, he led the campaign of 1406–07 in Guienne, but failed before Blaye. The heavy cost of these adventures and of Louis's court life, the increase of taxation and also Louis's rapacity (he acquired Angoumois, Périgord and the county of Blois), as well as his connection with the queen (Isabeau of Bavaria), whose lover he probably was, made him extremely unpopular. Philip the Bold's death had strengthened his position, but later his quarrel with Philip's son John the Fearless became acute. In 1405 both parties prepared for war, but a reconciliation was brought about on Oct. 16. However, on Nov. 23, 1407, Louis was murdered in Paris by John's retainers. Louis had eight children by his wife, including his successor, the poet Charles of Orléans. One of his natural sons was the famous bastard of Orléans, John, count of Dunois.

(F. CT.)

ORLEANS, LOUIS. DUKE OF (1703–1752), only son of Duke Philip II, the regent Orléans, was born at Versailles on Aug. 4, 1703. He took very little part in the politics of the time, although he was conspicuous for his hostility to Cardinal Dubois in 1723. In 1730 Cardinal Fleury secured his dismissal from the position of colonel general of the infantry. He retired and spent his time mainly in translating the Psalms and the epistles of St. Paul. Having succeeded his father as duke of Orléans in 1723, he died in the abbey of St. Geneviève at Paris on Feb. 4, 1752. His wife Augusta (d. 1726), daughter of Louis William, margrave of Baden, bore him one son, Louis Philippe, who succeeded him.

ORLEANS, LOUIS PHILIPPE, DUKE OF (1725–1785), son of Louis, duke of Orléans, was born at Versailles on May 12, 1725, and was known as the duke of Chartres until his father's death in 1752. He served with the French armies in the campaigns of 1742, 1743 and 1744, and at the battle of Fontenoy in 1745, retiring to Bagnolet in 1757 and occupying his time with theatrical performances. He died at St. Assise on Nov. 18, 1785. The duke married Louise Henriette de Bourbon-Conti, who bore him a son Philippe (Egalité), duke of Orléans, and a daughter, who married the last duke of Bourbon. His second wife, Madame de Montesson, whom he married secretly in 1773, was an authoress of some repute. He had two natural sons, the abbot of St. Far and the abbot of St. Albin.

See *L'Automne d'un prince,* a collection of letters from the duke to his second wife ed. by J. Hermand (1910).

ORLEANS, LOUIS PHILIPPE JOSEPH, DUKE OF (1747–1793), called PHILIPPE EGALITÉ, son of Louis Philippe, duke of Orléans, and of Louise Henriette de Bourbon-Conti, was born at St. Cloud on April 13, 1747. Having borne the title of duke of Montpensier until his grandfather's death in 1752, he became duke of Chartres, and in 1769 married Louise Marie Adelaide de Bourbon-Penthièvre, daughter and heiress of the duke of Penthièvre, grand admiral of France. Her wealth made him the richest man in France, and he determined to play a part equal to that of his great-grandfather, the regent, whom he resembled in character and debauchery. As duke of Chartres he opposed the plans of René Maupeou in 1771, and was exiled to his country estate of Villers-Cotterets (Aisne). When Louis XVI came to the throne in 1774, Chartres still found himself looked on coldly at court. In 1778 he served in the squadron of the comte d'Orvilliers, but the queen obtained his removal from the navy and he was given the honorary post of colonel general of hussars. He then abandoned himself to pleasure; he often visited London, becoming an intimate friend of the prince of

Wales (afterward George IV). He made himself very popular in Paris by his gifts to the poor in time of famine, and by throwing open the gardens of the Palais Royal to the people. Before the meeting of the notables in 1787 he had succeeded his father as duke of Orléans, and advertised his liberalism so boldly that he was believed to be aiming at becoming constitutional king of France. In November he was again exiled to Villers-Cotterets. He was elected to the states-general and led the minority of 47 noblemen who seceded from their own estate (June 1789) and joined the Tiers Etat. The part he played during the summer of 1789 is one of the most debated points in the history of the French Revolution. The court accused him of being at the bottom of every popular movement, and saw the "gold of Orléans" as the cause of the Reveillon riot and the taking of the Bastille. The best testimony for his behaviour during that summer is that of an English woman, Mrs. Grace Dalrymple Elliott, who shared his affections with the comtesse de Buffon; her statement shows that at the time of the riot of July 12 he was on a fishing excursion, and was rudely treated by the king on the next day when going to offer him his services. The marquis de la Fayette persuaded the king to send the duke to England on a mission and he remained in England from Oct. 1789 to July 1790. On July 7 he took his seat in the assembly, and on Oct. 2 both he and the comte de Mirabeau were declared by the assembly entirely free of any complicity in the events of October. He now tried to avoid politics, but the court suspected him and his friends talked about his being king. He made no attempt to get himself made king, regent or lieutenant general of the kingdom at the time of the flight to Varennes in June 1791, but again tried in vain to make his peace with the court in Jan. 1792. In the summer of that year he was present for a short time with the army of the north, but had returned to Paris before Aug. 10. After that day he ran great risks in saving fugitives; in particular, he saved the life of the count of Champcenetz, the governor of the Tuileries, his personal enemy, at the request of Mrs. Elliott. After accepting the title of Citoyen Egalité, conferred on him by the commune of Paris, he was elected 20th and last deputy for Paris to the convention. In that body he sat as quietly as in the national assembly, but at the king's trial he had to speak, and then only to give his vote for the death of Louis. Nevertheless, when the news of the desertion of his eldest son, the duke of Chartres, with Charles Dumouriez became known in Paris, all the Bourbons remaining in France, including Egalité, were arrested April 5. He remained in prison until October, when the Reign of Terror began, and was decreed "of accusation" on Oct. 3. He was tried on Nov. 6, and guillotined on the same day. Personally Orléans possessed the charming manners of a polished grand seigneur; he was debauched and cynical, but never rude or cruel, full of gentle consideration for all about him but selfish in his pursuit of pleasure.

ORLEANS, LOUIS PHILIPPE ROBERT, Duke of (1869–1926), eldest son of the comte de Paris, was born at York House, Twickenham, Eng., on Feb. 6, 1869. The law of exile against the French princes having been abrogated in 1871, he returned to France and was educated at Eu and at the Collège Stanislas, Paris. On the death of the comte de Chambord, the comte de Paris became head of the Bourbons; and in 1886 he and his son were exiled from France by the new law of 1886. He then passed through the Royal Military college, Sandhurst, Eng., and received a commission in the 4th battalion of the 60th Rifles, then quartered in India. In Jan. 1888 the duke joined his regiment for a few months. On attaining his majority, he went to Paris (Feb. 7, 1890), and, proceeding to the *mairie,* expressed his desire, as a Frenchman, to perform his military service. He was arrested in conformity with the law of 1886, tried and sentenced to two years' imprisonment; but he was liberated by Pres. Sadi Carnot after a few months' nominal incarceration (June 4), and conducted to the Swiss frontier. This escapade won for him the title of "Le Premier Conscrit de France." After the comte de Paris's funeral (Sept. 12, 1894) the duke received his adherents in London, and was accepted as the head of his house. On Nov. 5, 1896, he married the archduchess Maria Dorothea Amalia of Austria; there was no issue of the marriage. The duke of Orléans was interested in exploration, and published *Une croisière au Spitzberg* (1905). He died on March 28, 1926.

ORLEANS, PHILIP I, Duke of (1640–1701), son of the French king Louis XIII, was born at St. Germain-en-Laye on Sept. 21, 1640. In 1661 he was created duke of Orléans, and married Henrietta, sister of Charles II of England; but the marriage was not happy, and the death of the duchess in 1670 was attributed to poison. Later he married Charlotte Elizabeth, daughter of Charles Louis, elector palatine of the Rhine. Having fought with distinction in Flanders in 1667, Orléans returned to military life in 1672, and in 1677 gained a great victory at Cassel and took St. Omer. Louis XIV, it was said, was jealous of his brother's success; Orléans never commanded an army again. He died at St. Cloud on June 8, 1701, leaving a son, Philip, the regent Orléans, and two daughters: Anne Marie (1669–1728), wife of Victor Amadeus II, duke of Savoy; and Elizabeth Charlotte (1676–1744), wife of Leopold, duke of Lorraine. His eldest daughter, Marie Louise (1662–1689), wife of Charles II of Spain, died before her father.

ORLEANS, PHILIP II, Duke of (1674–1723), regent of France, son of Philip I, duke of Orléans, and his second wife, the princess palatine, was born on Aug. 2, 1674, and fought at the siege of Mons in 1691. His marriage with Mlle. de Blois, the legitimized daughter of Louis XIV, won him the favour of the king. He fought at Steinkerk, Neerwinden and Namur (1692–95). During the next few years he studied natural science. He was next given a command in Italy (1706) and in Spain (1707–08), where he gained some important successes, but his suspected desire to succeed Philip V on the throne of Spain gained him Louis XIV's disfavour. In Louis's will, however, he was appointed president of the council of regency of the young king Louis XV (1715). After the death of the king, Orléans had the will annulled by the *parlement,* and himself invested with absolute power. At first he made a good use of this, counselling economy, decreasing taxation, disbanding 25,000 soldiers and restoring liberty to the persecuted Jansenists. But the inquisitorial measures which he had begun against the financiers led to disturbances. He also countenanced the risky operations of the banker John Law (1717), whose bankruptcy led to a disastrous crisis.

A conspiracy under the inspiration of Cardinal Alberoni, first minister of Spain, to transfer the regency from Orléans to Philip V of Spain was discovered and defeated in 1718. Dubois, formerly tutor to the duke of Orléans and now his all-powerful minister, caused war to be declared against Spain, with the support of the emperor, and of England and the Netherlands (Quadruple alliance). Philip V made peace with the regent in 1720.

On the majority of the king (Feb. 15, 1723), the duke of Orléans resigned the supreme power; but he became first minister to the king, and remained in office till his death on Dec. 23, 1723. The regent had great qualities, both brilliant and solid, but his dissolute manners found only too many imitators, and the regency was one of the most corrupt periods in French history.

Bibliography.—J. B. H. R. Capefigue, *Histoire de Philippe d'Orléans, régent de France* (2 vols., 1838); A. Baudrillart, *Philippe V. et la cour de France,* vol. ii. (1890); and L. Wiesener, *Le régent, l'abbé Dubois et les Anglais* (3 vols., 1891–99).

ORLEANS (Orleans), a city of France, the chief town of Loiret, on the Loire, 77 mi. S.S.W. of Paris by rail. Pop. (1946) 70,240. Les Aubrais, 1 mi. to the north, is one of the chief railway junctions in the country. An early trading post among the Gauls, Orléans was known as *Genabum* by the Romans, and its people led the revolt against Julius Caesar in 52 B.C. In the 5th century it had taken the name *Aurelianum* from either Marcus Aurelius or Aurelian. It was vainly besieged in 451 by Attila, and by Odoacer in 471, but Clovis took it in 498 and held there in 511 the first ecclesiastical council in France. It then became the capital of a separate kingdom, but was united with that of Paris in 613. In the 10th century the town was given in fief to the counts of Paris, who in 987 ousted the Carolingians. Philip, fifth son of Philip VI, was the first duke of Orléans. After the assassination of his successor, Louis, the people of Orléans sided with the Armagnacs, and thus brought upon themselves the attacks of the Burgundians and the English. Joan of Arc relieved the city in 1429. In 1562 it became the headquarters of Louis I of Bourbon, prince of Condé, the Protestant commander in chief. In 1563 Francis, duke of Guise, laid siege to it, but was assassinated. Orléans was surrendered to the king, who raised the fortifications. It was held by the Huguenots from 1567 to 1568. The St. Bartholomew massacre there in 1572 lasted a week. It

was given as a *lieu de sûreté* to the League under Henry III, but surrendered to Henry IV in person in 1594. The town is surrounded by boulevards, and is connected with the suburb of St. Marceau by an 18th century stone bridge of nine arches. The river is canalized on the right, and serves as a continuation of the Orléans canal.

In the Place du Martroi is a statue of Joan of Arc. A simple cross marks the site, on the left bank of the Loire, of the *Fort des Tourelles,* captured by Joan of Arc in 1429. The cathedral of Ste. Croix, begun in 1287, was burned by the Huguenots in 1567 before its completion. Henry IV, in 1601, laid the first stone, the building of which continued until 1829. The church of St. Aignan mutilated by the Protestants consists of a transept and choir of the second half of the 15th century; it contains in a gilded and carved wooden shrine the remains of its patron saint. St. Euverte, dedicated to one of the oldest bishops of Orléans (d. 391), is an early Gothic building dating from the 13th, completely restored in the 15th century. The church of St. Paul (15th and 16th century) has an isolated tower, and Notre-Dame de Recouvrance was rebuilt between 1517 and 1519 in the Renaissance style and dedicated to the memory of the deliverance of the city. The *hôtel de ville,* built under Francis I and Henry II and restored in the 19th century, was formerly the residence of the governors of Orléans, and was occupied by the kings and queens of France from Francis II to Henry IV. The public library comprises among its manuscripts a number dating from the 7th century. The *salle des fêtes,* formerly the corn-market, stands within a vast cloister formed by 15th-century arcades, once belonging to the old cemetery. Among old houses are that of Agnès Sorel (15th and 16th centuries), containing objects relating to Joan of Arc, that of Francis I, of the first half of the 16th century, that occupied by Joan of Arc during the siege of 1429, and that known as the house of Diane de Poitiers (16th century), which contains the historical museum. The anniversary of the raising of the siege in 1429 by Joan of Arc is celebrated yearly. Orléans is the seat of a bishopric under the archbishop of Paris, a prefect, a court of appeal, and a court of assizes and headquarters of the V army corps.

The more important industries are the manufacture of tobacco (by the state), blankets, pins, vinegar, machinery, agricultural implements, hosiery, tools and ironware, and the preparation of preserved vegetables. Wine, wool, grain and live stock are commercial staples, round which there are important nurseries.

ORLÉANS CAMPAIGN OF 1870

Orléans was the pivot of the second phase of the Franco-German War, called the "People's War," when the new armies began their attempt to relieve Paris. After the fall of the empire, the Government of National Defense, deciding to remain in Paris, delegated three of its members, Crémieux, Glais-Bizoin and Fourichon, proceeded to the provinces to hasten the levy of troops. General de la Motte-Rouge was appointed to command the "territorial division of Tours." From many scattered units, most of them ill equipped, he formed the XV corps. The Germans, however, were only able to spare the I Bavarian corps and three cavalry divisions (2nd, 4th and 6th), the investment of Paris and Metz occupying their forces. On Oct. 5 the German 4th cavalry division was forced to retire before a French detachment under Reyau. Von der Tann, commanding the I Bavarian corps, was reinforced by the 22nd infantry and 2nd and 6th cavalry divisions. Reyau was attacked at Artenay on Oct. 10 and was thrown back in disorder, Orléans being captured in the evening of the following day, whereupon the French fell back on Sologne. Meanwhile Gambetta, minister of defense, arriving at Tours by balloon from Paris, assumed virtual control on Oct. 11, being aided by De Freycinet, the deputy minister. He forthwith appointed General d'Aurelle de Paladines in place of La Motte-Rouge. The change gave impetus to the training and reorganization of the troops and by Oct. 23 a further force was concentrated at Blois, which formed the XVI corps.

After the withdrawal of the 22nd infantry division from Von der Tann, its commander, General Wittich advanced to Châteaudun which he captured on Oct. 18. He now made for Chartres, which also fell into his hands. The resistance he had met with led the Germans to believe in the existence of a new army as the French who defended them did not belong to either the XV or XVI corps. The "Army of the West," as they called this phantom force, originated from the defenders of Châteaudun and Chartres and was never formed into a fighting unit.

The French command decided to advance against the Germans massed around Orléans whom it mistakenly estimated at 60,000 men, whereas they barely numbered 26,000. As a mystification empty trains were run to Le Mans to confirm the Germans in their belief in the existence of an army west of Paris. But the contemplated offensive was postponed owing to bad weather and the discouraging news of Bazaine's capitulation with his 150,000 troops at Metz.

Moltke directed the II army, released from the siege of Metz, towards Bourges, sending it by Chalon-sur-Saône, while he formed a new detachment under the grand duke of Mecklenburg-Schwerin consisting of the I Bavarian army corps, 17th and 22nd infantry and 2nd, 3rd and 4th cavalry divisions. This force was to concentrate between Châteaudun and Chartres.

The French advance began auspiciously, the German cavalry retiring before them on Nov. 8. The following day, moving across the country in battle formation, the French attacked Von der Tann who was drawn up at Coulmiers, forcing him to retreat unpursued. The 2,500 Germans guarding Orléans thereupon evacuated the city and joined Von der Tann at Angerville.

Meanwhile, the grand duke with his detachment had not encountered any strong hostile forces and by Nov. 19 Moltke began to believe that after all the French must still be concentrated in the neighbourhood of Orléans to the number of 150,000 men. He fully realized the gravity of the situation—the expected sortie from Paris coupled with the advance of the army of the Loire. The king of Prussia was prepared, as he said to Waldersee at Versailles, to raise the siege of Paris if the II army sustained a defeat.

The members of the government in Paris urged Trochu, the governor, to attempt a sortie toward Fontainebleau, thereby joining hands with the army of the Loire. The sortie was to begin Nov. 29, but the balloon carrying the message to Gambetta alighted in Norway, which caused a delay. D'Aurelle still remained on the defensive near Orléans though pressed by Freycinet to advance.

The battle of Beaune-la-Rolande took place on Nov. 28, General Crouzat's XX corps attacking the German X corps between Turanville and Beaune-la-Rolande, while Billot's XVIII corps pushed back the Prussian left. In the afternoon Crouzat was himself assailed in the rear from Pithiviers by a cavalry and infantry division, Billot also falling back.

After further operations in which the French sustained defeat, the Germans moved toward Orléans on Dec. 3 in a scythe-like line of battle 40 miles long. Serious resistance was only encountered at Chilleurs. Orléans was entered on Dec. 4th. (*See* further FRANCO-GERMAN WAR.)

ORLEY, BERNARD VAN (*c.* 1490–1540), Flemish painter, son of the painter, Valentyn van Orley, was born at Brussels about 1490. The date of his birth is estimated from his portrait by Dürer painted in 1521, now in the Dresden gallery. It represents an attractive and intelligent man of about 30. In 1515 he was employed by Margaret of Austria, then regent of the Netherlands, and three years later he was appointed her court painter. He died in 1540. His earliest important work is the altarpiece of SS. Thomas and Matthias, of which the centrepiece is at Vienna and the wings at Brussels painted about 1512. The style of the picture seems to be inspired by the school of Autrey. From 1516–22 Bernard van Orley imitated Mabuse—to this period belongs the "Madonna" in the Wied collection and the "Holy Family" in the Louvre. In the "Holy Family" in the Prado (1522) the influence of Mabuse has given way to that of Raphael. In the altarpiece representing the "Patience of Job," (1521) now in the Brussels gallery, we find the two influences combined. The artist had many opportunities to see designs by Raphael whose tapestry cartoons were in Brussels for many years. Important works of his later period are the "Hanneton

Family" altarpiece in the Brussels gallery; the "Last Judgment" (1525) at Antwerp; and the "Crucifixion" at Rotterdam. He painted several portraits; the one of Dr. Georg Zelk in the Brussels gallery is the only one which is signed and dated (1519). Van Orley was a designer of tapestries; for instance, "Hunts of Maximilian," in the Louvre, and "Victory of Pavia" at Naples.

See M. Friedlander, *Annual of Prussian Museums* (1908–09).

ORLOV, ALEXIS FEDOROVICH, Prince (1787–1862), Russian statesman, natural son of Count Theodore Grigorievich Orlov, took part in all the Napoleonic wars from 1805 to the capture of Paris. For his services as commander of the cavalry regiment of the Life Guards on the occasion of the rebellion of 1825 he was created a count, and in the Turkish War of 1828–29 rose to the rank of lieutenant-general. Orlov was the Russian plenipotentiary at the Peace of Adrianople, and in 1833 was appointed Russian ambassador at Constantinople, holding at the same time the post of commander-in-chief of the Black Sea Fleet. He was one of the most trusted agents of Nicholas I., whom in 1837 he accompanied on his foreign tour. In 1854 he was sent to Vienna to bring Austria over to the side of Russia, but without success. In 1856 he was one of the plenipotentiaries who concluded the Peace of Paris, and was rewarded with the dignity of prince, and the presidency of the imperial council of state and of the council of ministers. In 1857 he presided over the commission formed to consider the question of the emancipation of the serfs, to which he was altogether hostile.

ORLOV, ALEXIS GRIGORIEVICH, Count (1737–1808), brother of Gregory, Count Orlov (*q.v.*), was remarkable for his athletic strength and dexterity. In the revolution of 1762 he played an even more important part than his brother. He conveyed Peter III. to the château of Ropsha and is said to have murdered him there. In 1770 he was appointed commander-in-chief of the fleet sent against the Turks, whose far superior navy he annihilated at Cheshme (July 5, 1770), a victory which led to the conquest of the Greek archipelago. He devoted himself to horse-breeding, and produced the finest race of horses then known by crossing Arab and Frisian, and Arab and English studs. In the war with Napoleon during 1806–07 Orlov commanded the militia of the fifth district, which was placed on a war footing almost entirely at his own expense. He left an estate worth five millions of roubles and 30,000 serfs.

See article, "The Associates of Catherine II.," No. 2, in *Russkaya Starina* (Rus.) (St. Petersburg, 1873).

ORLOV, GREGORY (Grigorii) **GRIGORIEVICH,** Count (1734–1783), Russian statesman, was the son of Gregory Orlov, governor of Great Novgorod. While serving in the capital as an artillery officer he caught the fancy of Catherine II., and was the leader of the conspiracy which resulted in the dethronement and death of Peter III. (1762). Catherine made him a count and adjutant-general, director-general of engineers and general-in-chief. At one time the empress thought of marrying her favourite, but the plan was frustrated by Nikita Panin. Orlov's influence became paramount after the discovery of the Khitrovo plot to murder the whole Orlov family. Gregory Orlov entered with enthusiasm, both from patriotic and from economic motives, into the question of the improvement of the condition of the serfs and their partial emancipation. He was their advocate in the great commission of 1767. One of the earliest propagandists of the Slavophil idea of the emancipation of the Christians from the Turkish yoke, he was sent as first Russian plenipotentiary to the peace-congress of Focsani (1771), but he failed in his mission, owing partly to the obstinacy of the Turks, and partly (according to Panin) to his own insolence. He was superseded in the empress's favour by Vasil'chikov.

See A. P. Barsukov, *Narratives from Russian History in the 18th Century* (Rus.) (St. Petersburg, 1885).

ORLOV, NIKOLAI ALEKSYEEVICH, Prince (1827–1885), entered the diplomatic service, and represented Russia successively at Brussels (1860–1870), Paris (1870–1882) and Berlin (1882–1885). As a publicist he stood in the forefront of reform. His articles on corporal punishment, which appeared in *Russkaya Starina* in 1881, brought about its abolition. He also advocated tolerance towards the dissenters. He wrote a *Sketch of Three Weeks' Campaign in 1806* (St. Petersburg, 1856).

ORLOV, THEODORE (Fedor) **GRIGORIEVICH,** Count (1741–1790), Russian general, participated with his elder brothers, Gregory (*q.v.*) and Alexis (*q.v.*), in the *coup d'état* of 1762, after which he was appointed chief procurator of the senate. His naval exploits in the first Turkish War were commemorated by a triumphal column, crowned with naval trophies, erected at Tsarskoe Selo. He retired in 1775.

ORM or **ORMIN,** the author of an English book, called by himself *Ormulum* ("because Orm made it"), consisting of metrical homilies on the gospels read at mass. The unique ms., now in the Bodleian library, is certainly Orm's autograph, and contains abundant corrections by his own hand. On palaeographical grounds it is referred to about A.D. 1200, and this date is supported by the linguistic evidence. The dialect is midland, with some northern features. The orthography of the *Ormulum* is the most valuable existing source of information on the development of sound in Middle English. On the whole, the language of the *Ormulum* seems to point to north Lincolnshire as the author's native district. There are reasons for thinking that Orm and the Walter to whom it is dedicated may have been inmates of the Augustinian priory of Elsham, near the Humber, which was established about the middle of the 12th century by Walter de Amundeville.

The *Ormulum* is written in lines alternately of eight and seven syllables, without either rhyme or alliteration. The rhythm may be seen from the opening couplet:

Nu, broþerr Wallter, broþerr min
Affterr þe flæshess kinde.

The extant portion of the work, not including the dedication and introduction, consists of about 20,000 lines. But the table of contents refers to 242 homilies, of which only 31 are preserved; and as the dedication implies that the book had been completed, and that it included homilies on the gospels for nearly all the year, it would seem that the huge fragment which we possess is not much more than one-eighth of this extraordinary monument of pious industry.

The *Ormulum* was edited for the first time by R. M. White in 1852. A revised edition, by R. Holt, was published in 1878. Many important corrections of the text were given by E. Kölbing in the first volume of *Englische Studien*. With reference to the three forms of the letter g, *see* A. S. Napier, *Notes on the Orthography of the Ormulum*, printed with *A History of the Holy Rood Tree* (Early English Text Society, 1894).

ORME, ROBERT (1728–1801), English historian of India, was born at Anjengo on the Malabar coast on Dec. 25, 1728, the son of a surgeon in the Company's service. Educated at Harrow, he was appointed to a writership in Bengal in 1743. He returned to England in 1753 in the same ship with Clive, with whom he formed a close friendship. From 1754 to 1758 he was a member of council at Madras. His great work was *A History of the Military Transactions of the British Nation in Indostan from 1745* (3 vols., 1763–78). This was followed by a volume of *Historical Fragments* (1781), dealing with an earlier period. In 1769 he was appointed historiographer to the East India Company. He died at Ealing on Jan. 13, 1801. His valuable collections of mss. are in the India Office library. Not a few of the most picturesque passages in Macaulay's Essay on Clive are borrowed from Orme.

ORMER, the name given in the Channel Isles and on the coasts of France to *Haliotis tuberculata,* a gastropod mollusc. It has a shell with a widely open aperture, more or less resembling a human ear in outline. The animal lives beneath stones and rocks close to the low-water mark of spring tides. For a sedentary organism it can move remarkably fast, and observers have commented on its strength and agility. The ormer is an article of human food in the Channel Isles and elsewhere (*see* Abalone). The States of Guernsey introduced legislation in 1926 for its protection.

See T. A. Stephenson (1924), *Journ. Marine Biol. Assocn.*, xiii. No. 2, p. 480.

ORMEROD, ELEANOR A. (1828–1901), English entomologist, the daughter of George Ormerod, F.R.S., author of *The History of Cheshire,* was born at Sedbury Park, Gloucestershire,

on May 11, 1828. The opportunity afforded for entomological study by the large estate upon which she grew up and the interest she took in agriculture soon made her an authority upon this subject. In 1868, she aided the Royal Horticultural Society in forming a collection of insect pests of the farm for practical purposes, and was awarded the Flora medal of the society. In 1877 she issued a pamphlet, *Notes for Observations on Injurious Insects,* which was distributed among persons interested in this line of inquiry, who readily sent in the results of their researches, and was thus the beginning of the well-known *Annual Series of Reports on Injurious Insects and Farm Pests.* In 1881 Miss Ormerod published a special report upon the "turnip-fly," and she was consulting entomologist to the Royal Agricultural Society from 1882 to 1892. For several years she was lecturer on scientific entomology at the Royal Agricultural college, Cirencester. Eleanor Ormerod died at St. Albans on July 19, 1901.

Her works include: *The Cobden Journals; Manual of Injurious Insects; Handbook of Insects Injurious to Orchard and Bush Fruits;* and her *Autobiography and Correspondence* (1904). *See* also: *Canadian Entomologist,* vol. 33, 1901; *Royal Agric. Soc. Journ.* vol. 62, 1901.

ORMOC, a municipality (with administrative centre and 46 *barrios* or districts), of the island and province of Leyte, Philippine Islands, on the west coast about 35 mi. S.W. of Tacloban, the provincial capital. Pop. (1939), 77,349; 32 were whites. Ormoc is the centre of an extensive abacá- (Manila hemp) producing region and has a large coastwise trade, especially with Cebu. The vernacular is Cebuano. Of the inhabitants aged 6 to 19 inclusive, 18·4% in 1939 attended school, while 32·6% of the population 10 years old and over was literate.

ORMOLU, an alloy of copper and zinc, sometimes with an addition of tin. The name is also used to describe gilded brass or copper. The tint of ormolu approximates closely to that of gold; it is heightened by a wash of gold lacquer, by immersion in dilute sulphuric acid or by burnishing. The principal use of ormolu is for the mountings of furniture. With it the great French *ébénistes* of the 18th century obtained results which, in the most finished examples, are almost as fine as jewellers' work. The mounts were usually cast and then chiselled with extraordinary skill and delicacy. (*See* also SILVERSMITHS' AND GOLDSMITHS' WORK.)

ORMOND, a town of Volusia county, Florida, U.S.A., on the Halifax river (an arm of the Atlantic ocean extending along the east coast for 25 mi.) just N. of Daytona Beach. It is on federal highway 1 and is served by the Florida East Coast railway. The resident population was 3,350 in 1950; 1,914 in 1940, federal census. It is a winter resort with large hotels and beautiful residences. The hard, compact Ormond-Daytona beach (200 ft. wide and 20 mi. long), formerly the scene of automobile speed tests, is used by tourists, winter and summer, for bathing and motoring. Ormond was incorporated in 1880. Until his death in 1937, it was the winter home of John D. Rockefeller.

ORMONDE, EARL AND MARQUESS OF, titles still held by the famous Irish family of Butler (*q.v.*), the name being taken from a district now part of co. Tipperary. In 1328 James Butler (*c.* 1305–37), a son of Edmund Butler, was created earl of Ormonde, one reason for his elevation being that his wife Eleanor Bohun was a granddaughter of Edward I. His son James, the 2nd earl (1331–82), was four times governor of Ireland; the latter's grandson James, the 4th earl (d. 1452), held the same position several times, and won repute not only as a soldier, but as a scholar. His son, James, the 5th earl (1420–*c.* 1461), was created an English peer as earl of Wiltshire in 1449. He was lord high treasurer of England in 1455 and again in 1459, and was taken prisoner by the Yorkists after the battle of Towton in 1461. He and his two brothers were then attainted, and he died without issue, the exact date of his death being unknown. The attainder was repealed in the Irish parliament in 1476, when his brother Sir John Butler (*c.* 1422–78), who had been pardoned by Edward IV. a few years previously, became 6th earl of Ormonde. John, who was a fine linguist, served Edward IV. as ambassador to many European princes. His brother Thomas, the 7th earl (*c.* 1424–1515), a courtier and an English baron under Richard III. and Henry VII., was ambassador to France and to Burgundy; he left no sons, and on his death in August 1515 his earldom reverted to the crown.

Margaret, a daughter of this earl, married Sir William Boleyn of Blickling, and their son Sir Thomas Boleyn (1477–1539) was created earl of Ormonde and of Wiltshire in 1529. He arranged the preliminaries for the Field of the Cloth of Gold; he was lord privy seal from 1530 to 1536, and served the king in many other ways. He was the father of Anne Boleyn.

Meanwhile in 1515 the title of earl of Ormonde had been assumed by Sir Piers Butler (*c.* 1467–1539), a cousin of the 7th earl. He was lord deputy, and later lord treasurer of Ireland, and in 1528 he surrendered his claim to the earldom of Ormonde and was created earl of Ossory. Then in 1538 he was made earl of Ormonde, this being a new creation; however, he counts as the 8th earl of the Butler family. In 1550 his second son Richard (d. 1571) was created Viscount Mountgarret, a title still held by the Butlers. The 8th earl's son, James, the 9th earl (*c.* 1490–1546), lord high treasurer of Ireland, was created Viscount Thurles in 1536. In 1544 an act of parliament confirmed him in the possession of his earldom, which, for practical purposes, was declared to be the creation of 1328, and not of 1538.

Thomas, the 10th earl (1532–1614), a son of the 9th earl, was lord high treasurer of Ireland. He was a Protestant, and threw his great influence on the side of the English queen and her ministers in their efforts to crush the Irish rebels, but he was perhaps more anxious to prosecute a fierce feud with his hereditary foe, the earl of Desmond, this struggle between the two factions desolating Munster for many years. His successor was his nephew Walter (1569–1633), who was imprisoned from 1617 to 1625 for refusing to surrender the Ormonde estates to his cousin Elizabeth, the wife of Sir R. Preston and the only daughter of the 10th earl. He was deprived of the palatine rights in the county of Tipperary, which had belonged to his ancestors for 400 years, but he recovered many of the family estates after his release from prison in 1625.

Walter's grandson, James, the 12th earl, was created marquess of Ormonde in 1642 and duke of Ormonde in 1661 (*see* below); his son was Thomas Butler, earl of Ossory, and his grandson was James Butler, 2nd duke of Ormonde (*see* below).

When Charles Butler, earl of Arran (1671–1758), the brother and successor of the 2nd duke, died in December 1758, the dukedom and marquessate became extinct, but the earldom was claimed by a kinsman, John Butler (d. 1766). John's cousin, Walter (1703–83), inherited this claim, and Walter's son, John (1740–95), obtained a confirmation of it from the Irish House of Lords in 1791. He is reckoned as the 17th earl. His son Walter, the 18th earl (1770–1820), was created marquess of Ormonde in 1816, a title which became extinct on his death, but was revived in favour of his brother James (1774–1838) in 1825, and was retained by his descendants.

See J. H. Round on "The Earldoms of Ormonde" in Joseph Foster's *Collectanea Genealogica* (1881–83).

ORMONDE, JAMES BUTLER, 1ST DUKE OF (1610–1688), Irish statesman and soldier, eldest son of Thomas Butler, Viscount Thurles, and of Elizabeth, daughter of Sir John Poyntz, and grandson of Walter, 11th earl of Ormonde (*see* above), was born in London on Oct. 19, 1610. On the death of his father by drowning in 1619, the boy was made a royal ward by James I., removed from his Roman Catholic tutor, and placed in the household of Abbot, archbishop of Canterbury, with whom he stayed until 1625, residing afterwards in Ireland with his grandfather. In 1629, by his marriage with his cousin, the Lady Elizabeth Preston, daughter and heiress of Richard, earl of Desmond, he put an end to the long-standing quarrel between the families and united their estates. He succeeded his grandfather in 1632.

His active career began in 1633 with the arrival of Strafford, whom he supported consistently. In 1640 during Strafford's absence he was made commander-in-chief of the forces, and in August he was appointed lieutenant-general. On the outbreak of the rebellion in 1641 he rendered great service in the expedition to Naas, and in the march into the Pale in 1642, though much hampered by the lords justices, who were jealous of his power and

recalled him after he had succeeded in relieving Drogheda. On April 15, 1642, he gained the battle of Kilrush against Lord Mountgarret. He was created a marquess, and lieutenant-general with a commission direct from the king. He won the battle of New Ross (March 18, 1643) against Thomas Preston, afterward Viscount Tara. In September, the civil war in England having meanwhile broken out, Ormonde, in view of the successes of the rebels and the uncertain loyalty of the Scots in Ulster, concluded (Sept. 15) with the latter, in opposition to the lords justices, the "cessation" by which the greater part of Ireland was given up into the hands of the Catholic confederation, leaving only small districts on the east coast and around Cork, together with certain fortresses in the north and west then actually in their possession, to the English commanders. He subsequently, by the king's orders, despatched a body of troops into England (shortly afterward routed by Fairfax at Nantwich) and was appointed in Jan. 1644 lord lieutenant, with orders to keep the Scotch army occupied.

In the midst of all the plots and struggles of Scots, Old Irish, Catholic Irish of English race, and Protestants, and in spite of the intrigues of the pope's nuncio, as well as of attempts by the parliament's commissioners to ruin his power, Ormonde showed the greatest firmness and ability. He assisted Antrim in his unsuccessful expedition into Scotland. On March 28, 1646, he concluded a treaty with the Irish which granted religious concessions and removed various grievances. Meanwhile the difficulties of his position had been greatly increased by Glamorgan's treaty (Aug. 25, 1645) with the Roman Catholics, and it became clear that he could not long hope to hold Dublin against the Irish rebels. He thereupon applied to the English parliament, signed a treaty on June 19, 1647, gave Dublin into their hands upon terms and sailed for England at the beginning of August. He attended Charles during August and October at Hampton Court, but subsequently, in March 1648, in order to avoid arrest by the parliament, he joined the queen and prince of Wales at Paris. In September of the same year, he returned to Ireland to endeavour to unite all parties for the king. On Jan. 17, 1649, he concluded a peace with the rebels on the basis of the free exercise of their religion; on the execution of the king he proclaimed Charles II and was created a knight of the Garter in September. On the conquest of the island by Cromwell he returned to France in Dec. 1650.

Ormonde accompanied Charles to Aix and Cologne when expelled from France by Mazarin's treaty with Cromwell in 1655. In 1658 he went disguised, and at great risk, upon a secret mission into England. He attended the king at Fuenterrabia in 1659 and had an interview with Mazarin; and was actively engaged in the secret transactions immediately preceding the Restoration. On the return of the king he was at once appointed a commissioner for the treasury and the navy, and received other important places, together with an English peerage, and (1661) the dukedom of Ormonde in the Irish peerage. On Nov. 4, 1661 he once more received the lord lieutenantship of Ireland. The Act of Explanation (on land settlement) was passed through the Irish parliament by Ormonde in 1665. His heart was in his government, and he vehemently opposed the bill prohibiting the importation of Irish cattle which struck so fatal a blow at Irish trade; and retaliated by prohibiting the import into Ireland of Scottish commodities, and obtained leave to trade with foreign countries. He encouraged Irish manufactures and learning to the utmost, and it was to his efforts that the Irish College of Physicians owes its incorporation.

Faced by the loss of royal favour, Ormonde declared "However ill I may stand at court I am resolved to lye well in the chronicle." His irresponsible government was no doubt open to criticism. He had billeted soldiers on civilians, and had executed martial law. The impeachment, however, threatened by Buckingham in 1667 and 1668 fell through. Nevertheless by 1669 constant importunity had had its usual effect upon Charles, and in March Ormonde was dismissed. That year, he was, however, elected chancellor of Oxford university. On Dec. 6, 1670, an attempt was made to assassinate the duke by Thomas Blood. He was dragged out of his coach, and taken on horseback along Piccadilly with the intention of hanging him at Tyburn. Ormonde, however, succeeded in overcoming the horseman to whom he was bound, and his servants coming up, he escaped. The king pardoned Blood, and even treated him with favour after his apprehension while endeavouring to steal the crown jewels.

In 1671 Ormonde successfully opposed Richard Talbot's attempt to upset the Act of Settlement. In 1677 he was restored to favour and reappointed to the lord lieutenancy. On his arrival in Ireland he placed the revenue and the army upon a proper footing. In 1682 Charles summoned Ormonde to court. On Nov. 9, 1683 an English dukedom was conferred upon him, and in June 1684 he returned to Ireland; but he was recalled in October in consequence of fresh intrigues. Before, however, he could give up his government to Rochester, Charles II died; and Ormonde's last act as lord lieutenant was to proclaim James II in Dublin. Subsequently he lived at Cornbury in Oxfordshire. He refused the king his support over the Indulgence but James held him in respect. He died on July 21, 1688, and was buried in Westminster abbey.

ORMONDE, JAMES BUTLER, 2nd Duke of (1665–1745), Irish statesman and soldier, son of Thomas, earl of Ossory, and grandson of the 1st duke, was born in Dublin on April 29, 1665, and was educated in France and afterwards at Christ Church, Oxford. He commanded a regiment of horse in William's army at the battle of the Boyne. In 1691 he served on the continent under William, and after the accession of Anne he was placed in command of the land forces co-operating with Sir George Rooke in Spain. He succeeded Rochester as viceroy of Ireland in 1703, a post which he held till 1707.

On the dismissal of the duke of Marlborough in 1711, Ormonde was appointed captain-general in his place, and allowed himself to be made the tool of the Tory ministry, whose policy was to carry on the war in the Netherlands while giving secret orders to Ormonde to take no active part in supporting their allies under Prince Eugene. Though he had supported the revolution of 1688, Ormonde was traditionally a Tory, and Lord Bolingbroke was his political leader. During the last years of Queen Anne he almost certainly had Jacobite leanings, and corresponded with the duke of Berwick. He joined Bolingbroke and Oxford, however, in signing the proclamation of King George I, by whom he was nevertheless deprived of the captain-generalship. In June 1715 he was impeached, and fled to France, where he for some time resided with Bolingbroke, and in 1716 his immense estates were confiscated to the crown by act of parliament, though by a subsequent act his brother, Charles Butler, earl of Arran, was enabled to repurchase them. After taking part in the Jacobite invasion in 1715, Ormonde settled in Spain, where he was in favour at court and enjoyed a pension from the crown. He died on Nov. 16, 1745, and was buried in Westminster abbey.

See Thomas Carte, *Hist. of the Life of James, Duke of Ormonde,* 6 vols. (Oxford, 1851), which contains much information respecting the life of the second duke; Earl Stanhope, *Hist. of England, comprising the Reign of Queen Anne until the Peace of Utrecht* (1870); F. W. Wyon, *Hist. of Great Britain during the Reign of Queen Anne,* 2 vols. (1876); William Coxe, *Memoirs of Marlborough,* 3 vols., new edition (1847).

ORMSKIRK, a market town, urban district, Ormskirk parliamentary division, Lancashire, England, 11 mi. N.E. of Liverpool by the L.M.S.R. Pop. (1938) 18,400. Area, 24.4 sq.mi. The name and church existed in the time of Richard I, when the priory of Burscough was founded. Edward I granted the prior a char-

ter for a market at the manor of Ormskirk. On the dissolution of the monasteries the manor was granted to the earl of Derby.

The church of SS. Peter and Paul is a spacious building in various styles, principally Perpendicular. It possesses two western towers, the one square and embattled, the other octagonal and bearing a short spire. There are various Norman fragments, including a fine early window in the chancel. To the south-east of the church, is the Derby chapel, the property of the earls of Derby, whose vault is contained within. A grammar school was founded about 1614. Rope and twine making, iron-founding and brewing are carried on. The town has long been famous for its gingerbread, and is the centre of an important potato-growing district.

ORNAMENT, ARCHITECTURAL. In decorative art ornament is that element which supplies beauty in detail by the addition of anything which gives an aesthetic pleasure.

In all beginnings of primitive culture man shows a marked tendency to decorate his utensils, fabrics and ceramics with some sort of ornament. These early designs, consisting largely of overlapping stitches, lines, triangles, dots, zigzags, spirals and crosses, are purely linear even when colour is used to heighten the effectiveness of the designs. All have very similar motifs, and crude as this early ornament is, it still persists as a basis for much of the so-called abstract ornament in use to-day. These forms may be due to a lack of handicraft ability. For whether or not these early designs in the cultural growth of a people are representative of natural objects—the scales of fishes, the feather patterns of birds, plants and things of common everyday experience—the technical difficulties in the way of making free designs in the art of basketry, weaving or pottery tend to make the designs geometric in character. It is also possible that such designs may have lost their pure form through the tendency to standardize that comes of the endless copying by craftsmen of different degrees of skill. It is evident to the casual observer that more culture is necessary to produce free designs than is the case with the use and development of geometric art, because of the greater technical difficulties, and that naturalistic ornament while deriving its sources from nature tends to become abstract owing to the conventionalization of the motifs employed. At the same time, the abstract ornament tends to revert back to the natural as it takes on complexity.

The theory of the evolution of the natural to the geometric, while not accepted by all the authorities on primitive art, has, if the psychology of the designer or artist is taken into consideration, much to commend it. A conventionalization of design takes place without fail in any art due to the very great difficulty in inventing new motifs and to the natural inclination of the average craftsman to be content with imitation, and finally the design motifs conventionalize in primitive art because of a special symbolic meaning associated with the religion and customs of the tribe and so become difficult to change. In fact, it is this very conventionalization of ornament for all uses, for whatever reason, that formalizes into the standards which we call styles. Historically, these styles mark the evolution of ornamental design and are definitely related to the customs and civilization of the people who produced them. Furthermore, a style is known not by its beginnings but by its decadence, and is named not by its creator but by historians.

Influences.—All ornament is affected very strongly by the philosophy and thought of the time in which it is designed. It is interesting in that respect that primitive art fundamentally shows a clear desire on the part of the group design to express a complete and definite sense of fulfilment, a straightforward expression of a thing or things of the present only. Each unit or repeat in primitive design is wholly complete in itself and only establishes its relation as part of the whole through a very simple rhythm of the necessary repetition. And while it is true that primitive design may be very elaborate it is rarely complex but rather indicates a desire for richness. The slight degree of complexity that is gained is by the use of different primary colours added to the same linear motif or by increasing the number of rows of different patterns, each simple in itself.

Historically, all ornament has passed through this primitive stage to a period of larger viewpoint, when the artist becomes more interested in a sense of a lack of completeness and the design motifs gather or lose a quality of freshness and time appreciation in ratio to the existence or lack of that sense. For example, architectural ornament of the nature of the chevron, the dentil, the egg and dart, and the bead and reel, are primitive forms, each complete in itself, in which as a repetition the timebeat, the interval and the rhythm are uniform and are therefore rigid and mechanical, easily comprehended, and lacking in time appreciation; whereas such motifs as the arabesque, the vine and flamboyant tracery are without that limited sense of completeness, and in so far as the rhythm interacts with the interval and against the timebeat, they lose the quality of the mechanical and become more enduring in interest. (*See* Greek Architecture and Roman Architecture.)

Appreciation of any art presupposes sufficient leisure for its enjoyment, so that in designing ornament it would seem necessary to consider a time element as well as whether or not it is proper both as to position and technical fitness. This time element engenders space elements by means of which appreciation must be led from one detail to another, and as all ornament is static in nature it should include, therefore, within the design a stimulus toward, and an opportunity for, fresh viewpoints, and so encourage a more continuous period of appreciation. It is the thought or emotion behind the ornament that lives, while its surface aspects, because of the always evident desire to change, must become out-moded in time.

As all ornament is designed to form a pattern, whether it is composed of repeat units or as a general composition, the rhythms and interrelations of the structural background on which the ornamental detail is composed are as important as the primary functions of the design itself. It is this structure which gives coherence, unity and the sense of space and time to the ornamental design. In the consideration that all ornament must bear the repetition of being seen not only once but many times, the longer the element of time appreciation that is consciously set up within the design the more enduring in interest it will become. Yet it must not be so extended and involved as to be incomprehensible upon close inspection. It seems evident that a design whose rhythmic quality is purely mechanical, even though colour is used to superimpose an additional rhythm, must fail in possessing a sustained interest. The design motif fulfills its sole purpose when it creates a longer time interest in the object ornamented through its added beauty. This growth in time interest in appreciation of ornament is closely allied with the same growth in the complexity of the manners and philosophy of the people who are creating or modifying the ornamental design. A very clear conception of this interrelation of thought and design can be obtained from the study of the differences in growth of oriental and occidental ornamental motifs; the differences remain even when there are signs of influence of one thought upon the other, or through the gradual change from simplicity to complexity which is evident in the difference between the early ornament and thought of the Gothic period (*see* Gothic Architecture) and its later development. And while it is evident that the technical ability of the craftsman has contributed a great deal as to whether the design motifs are simple or complex—for instance, compare the wood carving of the Jacobean craftsmen with the work of Grinling Gibbons and the later English wood carvers—it would seem that the technical skill had but kept pace with the civilization with which it is associated, for as a civilization advances it is apparent that ornamental design becomes more complex rather than less, that the design motifs become fuller in nature, richer in detail and more nearly perfect in technique.

Materials.—It is generally thought that the treatment of ornament is definitely limited by and related to processes and materials, although throughout the history of ornament motifs and technique have been freely translated from one material to another without loss of harmony. The architectural motifs, for example, both structural and ornamental have always been used as pure ornament in the furniture and accessories of the same style. Ornamental design in which the design is not inherently manufactured

can be considered apart from the material it embellishes. The material of which the structure is built limits only the coarseness or fineness of the technique of the detail employed, although, for example, most stones or woods may be carved crudely or delicately according to the effect desired by the designer, the scale desired or the technical ability of the craftsman. This being so, the actual design motif may be thought of for its effect as such and is only limited in its possibilities by the thought and ability of the creator who might use it to obtain a difference in texture as a help in making a transition between two materials, or to create the pattern interest that comes from employing detail. In its relations to the material employed, it may be either structurally inherent or applied. Structural ornament is either integral, that is part of the structure as in weaving or where a structural member is changed for added grace, or as in veneers where the inherent pattern of wood or marble is used; whereas applied ornament may have little or no relation to the structure other than being placed upon it, and as its name implies is added later for pure embellishment.

Modern Tendency.—The ornament of the present, because of the almost immediate world-wide communication of ideas, is breaking away from the local or national boundaries and is becoming more universal in its characteristics. This will not necessarily lead to a tighter standardization because the means by which design is produced has undergone a great change. Since ornament has always had a very definite relation to the tools and technical ability of the period in which it is produced, it would seem natural that ornament, which is becoming more and more dependent upon the machine for its production and upon designers of greater perceptibility, will become less standardized because of the ease with which the tools are changed and improved, and as the self-consciousness of the designer in designing for the machine becomes less as the communities become more completely industrialized. This loss in standardization will tend to give a sense of greater freshness and creativeness in design and will give, because of the freedom in execution, a maximum individuality to the work of the designer.

For a complete list of the various architectural subjects treated in this work *see* ARCHITECTURAL ARTICLES.

ORNAMENTS, PRIMITIVE. The term "ornament" is strictly applied to objects worn from a sense of aesthetic value and intrinsic beauty either in gratification of the personal taste of the wearer, or in accord with fashion. But it can also be applied to objects which are worn for other reasons, such as the various objects worn for magico-religious reasons, as indications of social distinction and status, for the purpose of protection, as amulets and charms or even as curatives. As Professor Radcliffe Brown pointed out, the desire for protection and the desire for display "are very intimately related and are really both involved in every kind of ornament. All ornament in some way marks the relation of the individual to the society." (*Andaman Islanders,* p. 319.) Classes of ornaments in primitive society mark distinctions of sex and social status, the unmarried having ornaments peculiar to their status which differ conspicuously from those allowed to or required of married people. Articles worn as dress, that is, either for protection against climatic conditions, or from modesty may become ornaments if an element of aesthetic appreciation helps to determine individual choice or fashionable vogue. Decorations may be worked on or fashioned to plain materials to make the whole ornamental. In communities of a more permanent order, ornament and embellishment, external and internal, are applied to architecture in personal rivalry or in token of social status. To religious zeal is due the wealth of ornament often found in the Men's House—the centre of the communal life, the repository of the cult objects of the community, the origin of the temple.

The objects worn as ornaments are sometimes of a considerable degree of elaboration. Wings of butterflies, gorgeous tropical beetles, seeds, berries, flowers, variegated leaves, bright stones and all sorts of natural products are employed. The manufacture of ornaments as prescribed by the social order is an occupation of importance. Thus, "The Akamba wear a great number of ornaments (*mapa*) of various kinds, especially metal ones, but they never overload their bodies with them on ordinary occasions. On account of the composition and choice of colours these ornaments are attractive even to European ideas of beauty, and the fine execution of the work must arouse admiration." (G. Lindblom, *Akamba,* p. 375 [1920].) Nature provides the materials and the models. The sense of colour is expressed by using different coloured earths, the quest for which is a stimulus towards economic development. Conventionalization, vulgarization, degradation and imperfect, unintelligent imitations are notable in primitive art but at one and the same time in one community there may be artists of very different capacities.

ORNE, a department of the northwest of France, about half of which formerly belonged to the province of Normandy and the rest to the duchy of Alençon and to Perche. Pop. (1936) 269,331. Area, 2,372 sq.mi. West of the Orne and the railway from Argentan to Alençon lie primitive rocks connected with those of Brittany; to the east begin the Jurassic and Cretaceous formations of Normandy. The district of the newer rocks is rich agriculturally, that of the older rocks poor, but the whole department is relatively high land, by far the greater portion being over the 600-ft. contour (highest point, forest of Écouves, 1,368 ft.). It forms a centre whence rivers diverge in all directions, traversing deeply cut and picturesque valleys, in many cases well-wooded with fine oaks.

Horse breeding is very important in the rural districts; there are three breeds—those of Perche, Le Merlerault and Brittany. The great government stud of Le Pin (which was established in 1714), with its school of horse breeding, is situated between Le Merlerault and Argentan. A large number of lean cattle are bought in the neighbouring departments to be fattened; the farms near Vimoutiers, on the borders of Calvados, produce the famous Camembert cheese, and others produce excellent butter. The bee industry is very flourishing. Oats, wheat, barley and buckwheat are the chief cereals, and fodder in great quantity and variety, potatoes and some hemp are grown. The variety of production is due to the great natural diversity of the soils. Small farms are the rule, and the fields are surrounded by hedges relieved by pollarded trees. Along the roads or in the enclosures are numerous pear and apple trees, the latter yielding cider, part of which is manufactured into brandy. Orne has iron mines and freestone quarries; a kind of smoky quartz known as Alençon diamond is found. The hot springs of Bagnoles, which contain salt, sulphur and arsenic, are famous. In the forest of Bellême is the chalybeate spring of La Hesse, which was used by the Romans.

Cotton and linen weaving, notably at Flers (*q.v.*) and La Ferté-Macé (pop. [1936] 3,704), forms the staple industry of Orne. Alençon and Vimoutiers make linen and canvas. Vimoutiers has bleacheries, which, with dyeworks, are found in the textile centres. At Alençon only a little of the lace which takes its name from the town is still made. There are foundries and wireworks in the department, and articles in copper, zinc and lead are manufactured. Pins, needles, wire and hardware are produced at Laigle (pop. 5,145), and hardware also at Tinchebray. There are glass-works, paper mills, tanneries (the waters of the Orne being reputed to give a special quality to the leather), and gloveworks. Coal, raw cotton, metals and machinery are imported. The exports include woven and metal manufacture, livestock, farm produce.

The department is served by the Ouest-Etat railway. There are two arrondissements, with Alençon, the capital, and Argentan as their chief towns, 36 cantons and 513 communes. The department forms the diocese of Sées (province of Rouen) and part of

ORNAMENTAL DETAIL IN ARCHITECTURE

1. Taj Mahal, Agra, India; alabaster screen inlaid with precious stones enclosing the tombs of Shah Jahan and his empress, Mumtaz Mahal, for whom Shah Jahan built (*c.* A.D. 1631) the Taj Mahal. 2 Models of ornament for the Telephone Building, Washington, D C., an illustration of modern vertical design. 3. Sarcophagus from the tomb of Caecilia Metella, Augustan era; now in the court of the Farnese Palace, Rome. 4. Interior of *La Sainte-Chapelle*, Paris, built 1246–58 by Louis IX. (Saint Louis). (See *Gothic Architecture*, Plate I.) 5. Pillars of the Confucius Temple at Chu Fu, Shantung Province (Yuan dynasty, 1280–1368), with the Chinese dragon and other forms in high relief. 6. Entrance to the Transportation Building, Chicago World's Fair, 1893. Louis Sullivan, architect. 7. The Alhambra, Granada, Spain, 13th and 14th centuries; *mihrab* or prayer niche in the private mosque, adorned with lace-like carvings in stone of Arabic inscriptions, delicate arabesques, and geometric designs; and with horseshoe and lobar arch forms and coloured tiles, characteristic of Moorish art in Spain. 8. St. Mark's, Venice. Two isolated marble columns, near the arcades of the south side, brought in the 18th century, from St. Jean d'Acre, Palestine, by Tiepolo. 5th century, Hellenistic style. 9. Detail of a marble altar, by Benedetto da Rovezzano (1476–1556), in the Church of the Holy Trinity (Santa Trinità), Florence

the *académie* (educational division) of Caen, and the region of the IV army corps; its court of appeal is at Caen.

ORNITHOLOGY is the science of birds. We begin with the records of birds made by Aurignacian man during the last glacial epoch of the Ice age in France and Spain—paintings on the walls of caves, or figures or incisions carved on bits of horn, bone or stone. The birds that have been identified thus far from this remote Palaeolithic art include the crane, duck, goose, grouse, owl, partridge and swan. In the more recent Neolithic period, outlines of birds are more common, so that in the cave at Tajo Segura, in the province of Cadiz, southern Spain, Col. Willoughby Verner found figures of 12 species of birds, the great bustard, crane, duck, goose, raven, spoonbill, flamingo, purple gallinule, glossy ibis, stork, eagle and marsh harrier. To these archaeologists assign an antiquity of 6,000–8,000 years. The Palaeolithic designs are much older.

From a painting and a statuette of the common fowl from Egypt, made about 4400 B.C., it is believed that this bird was even then kept in captivity, while knowledge of the domesticated pigeon in the same country, according to Canon Tristram, goes back to the 5th dynasty, about 3500 B.C. Record of the use of pigeons as carriers of messages is found a little later. In a tomb of the 4th dynasty of about 3700 B.C., at Meidoum, in Egypt, Auguste Mariette discovered a fresco showing red-breasted and white-fronted geese, whose painted colours are said to be exactly like those seen in the two species to-day.

Early Writings.—There are many incidental references to birds in the Bible, those in the Old Testament being of considerable antiquity. The writings of Aristotle (384–322 B.C.), though they do not attempt to give a connected account, include statements (according to Sundevall) that concern about 170 species of birds. He obtained part of his information from still earlier writers whose works are lost. Pliny the elder (d. A.D. 79), in his *Historia Naturalis,* devoted Book X to birds, taking much from Aristotle. Aelian (d. about A.D. 140) made various notes on birds, compiled in part from older authors.

Early Saxon poets mention the gannet and several other birds of uncertain identity in songs current during the 6th and 7th centuries, and during the latter came early records of falconry, apparently introduced by the Saxons into Britain. About the middle of the 8th century the *Epistolae Sancti Bonifacie* informs us that Boniface, archbishop of Mons in Belgium, presented to Ethelbert, king of Kent, a hawk and two falcons. In the laws of Howel, king of Cambria, supposedly in the 10th century, there is statement of the hunting of the pheasant, and allusion to hawking. Incidental references to hunting with hawks are found in accounts of the activities of Athelstan, and of Edward the Confessor. Aelfric's *Vocabulary,* a list of words prepared in the 10th century, possibly for educational use, and another of somewhat later date, contain names of more than 100 birds, while in the *Colloquy of Aelfric,* a series of dialogues between a master and his pupils, are references to hunting with and training of hawks. In the writings and manuscripts of the 12th and 13th centuries are many references to hawking, descriptions of decoys in which ducks were captured alive, records of heronries and an account of a great flight of crossbills into England in the year 1251.

Following the invention of printing, William Turner published in 1544 a commentary on the birds of Aristotle and Pliny, prepared in accordance with treatment that was the forerunner of modern methods. This was followed in 1555 by Konrad von Gesner's *Historia Animalium,* whose third book dealt with birds and contained many original observations, as the author travelled extensively and recorded his impressions first-hand. Pierre Belon, whose *Histoire de la nature des oyseaux* appeared also in 1555, had considerable knowledge of the anatomy of birds, and seems to have been the first to correlate the various parts of the avian skeleton with those of man's.

In the joint observations of Francis Willughby and John Ray, published by the latter in 1678, after the death of Willughby, there is found a division of all known birds into two great groups of landfowl and waterfowl, an arbitrary classification that has been current to the present generation, though now superseded by a more modern grouping based on structural characters.

Linnaeus, the founder of the modern system of scientific names used in systematic zoology, began publication of his *Systema Naturae* in 1735. His attempt was to be terse and concise, and in 1758, in the 10th edition of his work, he proposed that each species of animal be designated by two names, the first of generic significance applying in most cases to a number of somewhat similar allied forms, and the second specific in nature and used in connection with the genus name for the species in question alone. (*See* ZOOLOGICAL NOMENCLATURE.) In recent years, a category of subspecies, or geographic races, designated by a third Latin term or subspecific name, has been added where required.

Natural history collections made in connection with the many exploring expeditions of the late 18th and early 19th centuries brought to Europe, particularly to England and France, many specimens of birds that greatly broadened knowledge of the ornithology of the world. In early explorations paintings or drawings were made of birds, or specimens were preserved in spirits, or sometimes dried as mummies. At the beginning of the 19th century, as travellers increased and interest in natural objects expanded, methods of preparing skins of birds were evolved that led finally to the making of what are known as scientific specimens, where the skin, with the feathers intact, is removed from the bird, leaving only the bones of the skull, wings, feet and base of the tail. The inner surface of the skin is poisoned, usually with arsenic, filled with cotton, tow or other light vegetable substance and dried after being wrapped or otherwise arranged so that it resembles a dead bird. By means of such preparations it is possible to assemble collections of birds that may be preserved indefinitely for continued study and examination. The growth of such collections and their expansion into museums, where birds were mounted in natural positions, changed completely the style and method of published treatises dealing with ornithology. To this time these had been mainly accounts and descriptions written from hearsay or memory, and involving constant repetition of the writings of previous authors. Such accounts were now in large measure supplanted by detailed statements regarding specimens secured during voyages, or monographs that brought together all available knowledge concerning genera, families, or larger groups of birds. The art of illustration was amplified, and many works contained series of coloured representations that delineated the bird under discussion more definitely than words. Among early writers of such illustrated works or monographs may be mentioned E. L. Daubenton, whose *Planches enluminées* contained 1,008 plates mainly on birds; F. le Vaillant, who published on hornbills, cotingas, birds of paradise and many others; L. J. P. Vieillot, who produced an array of volumes that dealt with the majority of the known birds of the world, and C. J. Temminck, who wrote on the pigeons and gallinaceous birds.

John James Audubon's *Birds of America,* in 4 vols. of elephant folio size, containing 435 plates, was published in London between 1827 and 1838, and was followed by his *Ornithological Biography,* in which, with the aid of William Macgillivray, he gave accounts of the habits of North American birds. The writings of John Gould, which began in 1832, covered descriptions and beautiful paintings in colour of birds of all parts of the world and included in all more than 40 folio volumes illustrated by more than 3,000 plates.

After the middle of the 19th century ornithological publications increased to a point where it becomes impossible briefly to enumerate them. In America increase of knowledge in ornithology subsequent to Audubon and Alexander Wilson (who was a contemporary of Audubon in the study of American birds and published an excellent and painstaking account of them) came rapidly with the appointment in 1850 of Spencer Fullerton Baird as assistant secretary of the Smithsonian institution. Baird's early years in this new position were coincident with the initiation of the great exploratory surveys, including the Hayden surveys and the survey of the 40th parallel of latitude, undertaken by the government to develop the western part of the United States. Baird established the U.S. National museum as a depository for specimens of all kinds belonging to the U.S. government, and arranged to send

naturalists with the different survey parties, with the result that large collections, particularly of birds and mammals, went to Washington, furnishing the material for many important reports.

Ornithological Societies.—As ornithologists increased in number, desire for discussion of their problems grew, to take shape finally in serials devoted to birds alone. Among the early periodicals that continue today there may be mentioned especially the *Journal für Ornithologie* begun in 1853, the *Ibis,* founded by the British Ornithologists' union in 1859, and the *Auk,* originated by the American Ornithologists' union in 1883. The last mentioned is a direct continuation of the *Bulletin* of the Nuttall Ornithological club, established by that organization in April 1876. The Zoological Society of London, especially in its earlier years, had a profound influence on the development of ornithology through the labours of its prosectors, particularly A. H. Garrod, W. A. Forbes and Frank E. Beddard, and through its publications, especially the *Proceedings of the Zoological Society of London,* and its precursor, the *Proceedings of the Committee of Science* and *Correspondence of the Zoological Society* (1830, etc.).

Today, there is an ornithological or similar society in most of the principal countries of the world. In 1947 there were more than 30 periodicals devoted to various phases of bird study alone. Of these, one of the most important to the ornithologist has been the *Zoological Record,* published annually after 1864 by the Zoological Society of London. The section devoted to Aves annually contains reference to more than 1,000 separate papers.

Bird Protection.—Another phase of ornithological interest that has obtained extended popular support in the past two decades is that of the protection of useful or harmless birds. (*See* BIRDS, PROTECTION OF; BIRD SANCTUARIES.) Legislation intended to restrict the killing of ducks, grouse and other birds considered as game, began in very early times, indication of recognition of the propriety of such action being found in the Old Testament (Deuteronomy, xxii, 6–7) where there is a prohibition against the killing of a bird on the nest.

In the laws of the Welsh king, Howel of Cambria, about the 10th century A.D., there are definitions of the various kinds of hunts, including the hunting of the pheasant. Such penalties as the loss of both eyes were provided by William, duke of Normandy, for peasants who had the temerity to kill game reserved for the nobility. Game protection was thus one of the early tenets of Anglo-Saxon law, and so came early to the new world, particularly to the United States, though, unfortunately, it has not been possible to show clearly the need for rigid protective measures until the destruction of game had greatly reduced valuable species of birds. In America protective measures to conserve valuable birds antedate the coming of the Caucasian, however, since the Inca rulers, recognizing the value of the sea birds of the coasts of Peru as producers of fertilizers, forbade anyone under penalty of death to enter or disturb their rookeries during the breeding season. For many years in America legislation for the protection of game birds was considered a local matter and was applied by states or territories individually. It became recognized that this procedure, through lack of uniformity, did not give proper protection to ducks, geese and other migratory game birds, which led finally to assumption by the federal government of control over nonsedentary species and a covenant with Great Britain known as the Migratory Bird treaty, arranged in 1916, which provided uniform regulations for the United States and Canada. The success of this measure was so pronounced that it attracted wide attention and led to a similar convention with Mexico concluded in 1937. This was followed in 1940 by an inter-American agreement among the American republics for nature protection in general.

As human interest in birds spread, there arose considerable feeling against the killing of small birds for food or game. It was realized that insectivorous birds were of benefit to man through their assistance in keeping down the abundance of insects injurious to agriculture, to which was coupled the aesthetic appeal of birds in general, through their beauty of form, colour and note, to the sympathetic and understanding mind. Use of the feathers of birds in decorative dress has been the custom from remote times, a custom that at the close of the last century culminated in a fashion that required the placing of stuffed skins or parts of skins of birds in more or less grotesque attitudes upon women's hats. The resultant demand for feathers led to the destruction of birds by the hundred thousand. Plume-hunting became a lucrative business, and led to search for strange and beautiful feathers throughout the world. Terns, gulls, herons, birds of paradise, hummingbirds, to say nothing of countless familiar songbirds, were slaughtered to supply an unthinking and somewhat senseless desire for decoration, a course that led to great diminution in numbers in many species of birds. The destruction wrought was especially rapid in species that breed in colonies. Herons, terns and grebes, brought together by the paramount instinct for reproduction, were held by their eggs or young to a limited area, and so were easy to kill in large numbers. As this killing entailed the loss of eggs and the starvation of young, these species suffered to such an extent that some almost disappeared as living forms. As understanding of the results of such brutal methods arose, there resulted a revulsion against this fashion which led to the formation of such bird-protective organizations as the National Audubon society which brought forcibly to public attention the evils of plume-hunting. This resulted in a partial change in fashion, and in legislation against plume importation and traffic. It is now generally recognized in England and the United States that bird protection is meritorious, a sentiment spreading rapidly to other countries so that international conventions have been held to promote it.

In connection with protective measures it is realized that the Caucasian race in its present civilization has modified natural environments to such an extent that many avian inhabitants of our earth are being crowded out of existence. To procure the continuance of interesting forms, some for their economic worth and some for their aesthetic interest, reservations or sanctuaries have been formed which birds may frequent without molestation. In Europe such preserves were made primarily to protect upland game birds and are thrown open to hunting at the proper season. In the United States reservations have been established to cover areas where herons, terns or similar birds nest and consist of low coastal islands, or swamp and marsh lands of little monetary value. Both types of sanctuary are now found in many countries.

The result of such protection, enforced in most instances by paid wardens, has been to increase the numbers of many birds. The egret and snowy heron, at one time reduced from a great multitude whose breeding colonies were so populous that, from a distance, they appeared like vast white blankets, to a condition where it was unusual to see a single individual, have become again common in extensive areas. Terns have returned to colonies that were deserted for years, and the pelican maintains its numbers in spite of much unthinking persecution.

In the United States after 1935 there was a tremendous expansion of the reservation program so that by 1944 there were 278 refuges covering 17,626,916 ac., under jurisdiction of the department of the interior. These reservations ranged in size from a few acres to several hundred square miles, while lighthouse reservations, national parks and similar tracts were designated as bird preserves. In addition, various states developed the idea of game sanctuaries which also became refuges for birds. Private sanctuaries also multiplied and afforded much protection; many were established as local enterprises by cities, towns or by groups of private individuals.

Economic Studies.—Early information on the economic value of birds was based largely on field observation of living birds, and many of the data obtained were erroneous. The method should be checked by the stomach examination, as developed largely by the bureau of biological survey, of the U.S. department of agriculture (now part of the fish and wildlife service, department of the interior). In this, a series of stomachs of any given species of bird is secured, so far as practicable, at intervals throughout the year, under as many varying conditions of life as possible. These contents are examined under a microscope with low magnification, and the different kinds of insects, seeds, bones or other materials sorted. There is thus afforded a picture of the actual

food preferences of the species concerned and the status of the bird is decided on this basis as useful or harmful. These data have been of great use in arranging protection for species that assist in the war on insects injurious to crops, or that are proved to be harmless, since such information offers a certain check against observations on living birds in the field. (*See* publications of the fish and wildlife service [*q.v.*] of the U.S. department of the interior.)

Aviculture.—Aviculture (*see* AVIARY AND AVICULTURE), or the keeping of birds alive, goes back to a remote period, of unknown date, when primitive man brought young birds of various kinds to his rude domicile, partly through curiosity and partly to use as food. Parrots are mentioned by Ctesias, a Greek writer, a century before the time of Aristotle, as birds that spoke the language of man, and a little later the Romans are known to have kept them in ornate, silver-wired cages of tortoise shell and ivory.

The domestication of falcons for hunting is recorded in Persia as early as 1700 B.C., and is said to have antedated that period in China. Falconry (*q.v.*) is believed to have spread to Europe as early as three centuries before the Christian era. In America the Pueblo Indians of New Mexico and Arizona held the turkey (*Meleagris gallopavo*) in captivity at least 1,000 years ago, and probably at a much earlier period, not for use as food, but for the feathers, which were plucked from the living bird and burned in prayer offerings to propitiate the Deity. The accumulations of turkey bones in a number of pueblo ruins indicate the numbers maintained.

The original canary (*Serinus serinus canarius*) is believed to have come from the Canary Islands, but in its original gray, olive-green and yellowish plumage, with sides and flanks streaked with dusky, is so similar to the serin finch (*Serinus serinus serinus*) of southern Europe that it is probable that both these closely related geographic races furnished the stock from which have come our modern birds. Canaries were known in a domesticated state at the close of the 14th century, though they seem at that time to have been rare, as Konrad von Gesner, in 1555, mentions that he had never seen one. Variation in colour among them began early, as partly yellow canaries were known at Nuernberg in 1614, and in 1677 pure yellow canaries as well as white ones were recorded at Augsburg. Modern interest in canaries is shown by the many societies of canary breeders and several journals that deal with their needs.

The keeping in captivity of exotic birds of all kinds originally was the field of zoological gardens, but has engaged the attention of many individuals and until World War II gained greatly in vogue, particularly in western Europe and in the United States. Aviaries were brought to a high state of perfection, and the requirements of many delicate species of birds were studied with the utmost care to permit success in their breeding and rearing in confinement, the highest goal of achievement of the bird fancier.

TYPES OF LIVING BIRDS

Mammals have specialized for life on land (as the deer and mouse), in water (as the whale), in the air (as the bat), for night life (as the lemur) and in the earth (as the mole). But birds specialize for existence or progression through the air. Though it is common for birds to nest in holes or tunnels in the earth, which, in many cases, are excavated specially for this purpose, no bird has been able to adapt itself to continuous life underground, probably because its covering of feathers is not designed to withstand the constant abrasion that would take place in burrowing. Also, though many birds frequent the water, none are so wholly adapted to life beneath the surface as the whales. The bird thus has failed to utilize completely the ecological environments that have been available for it—a manifestation of its inferior adaptability compared to the mammal.

Birds adapted to a terrestrial existence are found in many widely separated groups, as for example ostriches, bustards, plovers, larks and pipits. Most of these adopt a terrestrial habit to secure food and safety from enemies. They run about on the earth and, though the greater number retain power for flight, often trust to their legs to avoid or escape ordinary pursuit. Most of them show greatest variety in regions of extensive plains, prairies or broad, open downs. The wholly terrestrial forms that have entirely lost the power of flight are comparatively few, and (so far as continental areas are concerned) are birds of considerable size and strength. Among living forms they include the ostriches of Africa, which extend into Eurasia as far as southern Iran, the cassowaries of New Guinea and adjacent areas, the emus of Australia, the kiwis of New Zealand and the rheas of South America. These birds, though united by certain peculiarities, differ widely from one another and seem to represent ancient types of bird that were formerly more abundant, as a number of fossil forms are known. It will be noted that large flightless birds exist in modern times in all of the continents except North America, where they have not been represented since the Eocene.

The kiwis (*Apteryx*) of New Zealand, the queerest and most unbirdlike of living birds, are nocturnal and have different habits from the other species mentioned. They have long bills with the nostrils at the extreme tip, and move about by using the bill to test the ground before them as a blind man uses a cane, noting their surroundings partly by touch and partly by smell. On casual examination they seem to have no wings, but on investigation the wing is found concealed beneath the feathers, a tiny structure, a little more than three inches long when fully extended, and entirely without flying function, as the bird is heavier than an ordinary fowl. The cassowaries, like the kiwis, inhabit forest areas, but are far less peculiar. The wings are small, with heavy, naked quills nearly concealed beneath the long, hairlike feathers, and there is a curious casque on the head. It is said that the bird uses both casque and wing-quills to fend off entangling vines in travelling through the jungle.

Ostriches and rheas have larger wings and may extend them while running, but are wholly without power of flight. In all these birds the body is heavy and the legs are large and strong. With those fleetest in running there is a tendency to reduction in the number of toes, so that the rhea has three and the ostrich only two. That these birds have come from flying ancestors is apparently indicated by the wing, which, while small and weak, has the bones formed as in flying species. All the species discussed have the external surface of the breastbone smooth, without the great keel so characteristic of the flying birds, there being no necessity for such attachment, as in flightless birds the muscles usually concerned in flying have little development.

There is another type of terrestrial bird that has developed more recently than those just discussed, found mainly on oceanic islands. This includes various species of flightless rails, and some other birds that have lived under conditions in which they had no enemies from whom it has been necessary to escape by flying, so that through disuse the power of flight has been lessened until, finally, the birds are not able to rise from the ground, though the wing retains the same form encountered in flying birds and the breastbone still has a keel, though this may be greatly reduced in size. The weka rails of New Zealand are the most striking living examples of this group; they are nearly as large as a fowl, and run with great ease and rapidity. Some other flightless rails are much smaller, for example, the Laysan rail (*Porzanula palmeri*), of Laysan Island in the Hawaiian Islands, which is not much larger than a newly hatched chicken. In running fast this bird extends its wings and flaps them rapidly, but is unable to rise from the ground. Many other insular birds show a tendency to degeneration of the wing but still can fly.

Among birds adapted to life in the water, the penguins are preeminent. These include about 17 species found in southern seas, ranging in size from the great emperor penguin (*Aptenodytes forsteri*), which is 48 in. long and weighs up to 78 lb., to the little blue penguin (*Eudyptula minor*) of New Zealand and the Chatham Islands, which is only 16 in. in length. Penguins have thick, heavy bodies, more or less elongated, and are covered uniformly with dense, short feathers, without the bare spaces or apteria that in other birds divide the feather-growths into distinct tracts. The wing is a short, broad paddle, without developed quills, the feathers being close-set and stiff, almost like the scales of a reptile. In the water the penguin rests comparatively low.

Beneath the surface it progresses literally by flying, the flattened wings driving the bird through its aquatic medium swiftly and gracefully, while the feet are extended behind and serve as a rudder. Penguins have possessed their present type of body since early Tertiary times; but they came originally from a flying stock.

Other types of birds developed for life in the water include loons or divers and grebes, whose progress beneath the surface is accomplished, usually, by the use of the broad feet alone, the wings being held close to the sides, except when the birds are frightened or under other unusual circumstances. The downy young dive, by use of both wings and feet, indicating that flying under water is a primitive method. The many species of auks and guillemots use the wings beneath the surface as in the air above. The cormorant and the snakebird progress by use of feet alone. Mergansers, scaups, redheads, pochards and goldeneyes among ducks dive regularly with the feet alone, while in the same group old squaws, scoters and eiders as regularly use both wings and feet beneath the surface. The curious diving petrels (*Pelecanoides*) of the southern hemisphere fly swiftly beneath the water and may burst out through the surface in full flight.

Birds adapted for life at night are fairly numerous and are typified especially by members of the nightjar and owl families, though specialized forms occur among a number of other families. Most nocturnal birds have large eyes that usually reflect light with a prominent reddish colour so that the eyes of many nightjars glow like dull coals of fire by the reflected light of an electric torch and may be seen for a considerable distance. One of the American nighthawks (*Chordeiles acutipennis*) is an exception, since the eyes shine faintly with a yellowish green hue. Most nocturnal birds actually see at night by a specialized eye adapted to collect the faintest rays of light. Only the kiwis (*Apteryx*) among habitually nocturnal species appear almost blind.

GEOGRAPHIC DISTRIBUTION

The laws governing geographic distribution (*see* DISTRIBUTION OF ANIMALS), through which each faunal area has its own peculiar forms, apply to birds as to all other animals, in spite of the easy method of travel possible for the bird. Few birds are cosmopolitan. As an example may be mentioned the sanderling (*Crocethia alba*) which at some season may be found along water almost anywhere on the earth, but which nests only in the arctic regions, passing southward in migration throughout the world, to return in spring to its breeding area. The barn owl (*Tyto*), resident through wide areas in the temperate and tropical regions of the earth so that it reaches all the continents, has reacted to its environment in such a way that 50 geographic forms, some sufficiently distinct to be called species, were recognized by 1945. In contrast to this, many species are confined within very narrow limits, as the very distinct Laysan teal (*Anas laysanensis*), found only about the shores of one small lagoon on Laysan Island in the Hawaiian Bird reservation, where it has a range of only about 1 sq.mi.

Every continent has its peculiar forms of life, so that the earth's surface has been divided into great regions, each characterized by certain groups or by the lack of some found elsewhere. According to a usually accepted classification, these are given the following names: Nearctic region, for North America south to include the Mexican tableland; Neotropical region, for southern Mexico, Central and South America and the West Indies; Palaearctic region for Europe, Algeria and Morocco and Asia north of the Himalayas and the Gobi desert; Ethiopian region, for the remainder of Africa; Oriental region, for India, Indo-China, China, the Philippine Islands and the East Indian islands to, and including, Bali; Australian region, for Australia and the Pacific Islands south of the Tropic of Cancer; and New Zealand region, for New Zealand. The life of the northern hemisphere is so evidently allied that what are here designated Nearctic and Palaearctic regions are frequently united under the term Holarctic, a vast area that extends throughout the entire north temperate and arctic area.

These great regions, which cover continents, are divided into life-zones, where temperature and certain other general conditions control the distribution of species within narrower limits. The life-zones are more sharply delimited in temperate regions than in tropical and subtropical areas, and to some extent are more easily distinguished in the northern hemisphere than in the southern. They change with difference in altitude on the slopes of mountains as they do with difference in latitude in travelling north or south, and are most easily perceived on the slopes of steep mountains, where the successive zonal bands may be compared without great difficulty. Life-zones to the present time have been most intensively studied in North America. By the student the life-zone is further divided into faunas, where conditions imposed by rainfall, geological formation and similar factors produce sections characterized by aggregations of species or subspecies.

Birds, in general, have attained a vast distribution over the surface of the globe because of their ability in flight and their specialization for life on both land and water. As a result of this versatility and adaptability some form of bird is found at some season everywhere over the world, except perhaps in the centre of the great unexplored Antarctic continent. Broad areas of the sea, away from the great ocean currents that flow like rivers through this aquatic medium, may appear birdless for days and weeks, but are crossed at certain seasons by some of the petrels in their wanderings. The seas and lands within the Arctic circle are visited by many birds, some of which, as the raven and snow bunting, nest far north in Greenland, and some, as ducks and gulls, in summer traverse the solitudes of the north polar sea.

As individuals, birds may be tremendously abundant in temperate regions, but it is within the tropics that the greatest variety of forms occur within small limits. The largest aggregations are found in regions of diversified topography, where the life-zones change within a comparatively few miles from tropical to alpine. The greatest number of forms recorded as of 1945 from a limited area is that reported by Dr. Frank M. Chapman from Ecuador, where within approximately 75,000 sq.mi., an area less in extent than Great Britain, there are known at present 1,508 forms of birds, and this list is far from complete.

THE AVIAN LIFE-CYCLE

The circle of annual activities of any bird, in general, includes a period for nesting, the rearing of the young to maturity, and a subsequent resting time when a moult occurs to renew the covering of feathers. With many birds there is included in this program a migration or journey to some other region, and a subsequent return to the native area at the coming of a new breeding period. The cycle of activities thus corresponds to the seasonal round of the year, as the necessities of the bird are influenced by climatic conditions, which change from month to month, except in limited areas in the tropics, and even there the life of birds is influenced to a greater extent than might be imagined through the incidence of wet or dry seasons.

REPRODUCTION

With the approach of the breeding season there is instituted at once a conflict, active or passive, as the case may be, between males of the same kind for a breeding area in which, later, the nest will be located. (*See* also BIRDS: *Reproductive Habits.*) Each male selects some section suited to nesting needs and remains within or near it until a mate appears, if he is not already mated, and protects this tract against encroachment by others that may be considered rivals. In the case of gregarious species, like the sooty tern (*Sterna fuscata*) that nests in great colonies on islands in the sea, the nesting territory for each pair may be only a yard square, or even less, being a space in which the egg may be located, so that the incubating bird and her mate, on guard beside her, can not quite reach the adjacent pair with whom, and with any others that intrude, they spar and fight on the slightest provocation. The male red-winged blackbird (*Agelaius phoeniceus*) of North America, also gregarious, selects an area of marsh or swamp, with his neighbours situated at a distance of a few feet or a few yards, and remains on guard, forbidding entrance of another male in that limited space. Solitary species hold larger areas, so that a red-eyed vireo (*Vireo olivaceus*) may hold a clump of three or four trees, or a blackbird (*Turdus merula*) may

pre-empt a small section, including thickets, trees and open ground. Possession of such a breeding ground at the beginning of the nesting season is a paramount passion with each male, and to retain possession he will battle fiercely, even until death, with any others of his kind that may attempt definitely to locate within what have been selected as his limits. Under this urge, sanguinary combats are not unusual among species whose individuals live for the rest of the year wholly at peace with their kind.

Mating.—At the mating season the male bird resorts to a variety of artifices to attract attention on the part of the female, and to arouse her interest to the end that a nest be established. (*See* also COURTSHIP OF ANIMALS; SELECTION: *Sexual Selection;* BIRDS: *Reproductive Habits.*) Among perching birds this is first indicated by song (*q.v.*), by which the male not only gives expression to the pleasant sensations of merely living, but also, when established on his breeding ground, gives notice to rivals of his presence as a guard over his territory and advice to females that he is in search of a mate. The song may range from the polished effort of an expert, like many thrushes, the nightingale, or the mockingbird, to sounds that, to some human ears, may be merely disagreeable noise, as the chatter of the house sparrow, or the strange music of the plant cutter of South America (*Phytotoma rutila*), whose song is a curious squeaking that resembles exactly the rubbing produced by tree-limbs touching in the wind. The rhea booms, the hawk screams and the owl hoots, each producing music in the estimation of others of its kind.

Actual mating may be accompanied by a great variety of strange and unusual actions which the male alone, both sexes or more rarely the female alone may undertake (*see* COURTSHIP OF ANIMALS). The male ruffed grouse (*Bonasa umbellus*), of North America, selects a stand on some sheltered log or stump, to which he resorts each day to drum, a resonant love call for which he draws himself fully erect and begins a steady beat of his short, stiffly feathered wings. The action of these against the air between wing and body is so strong and abrupt that a dull thumping sound is produced, at first slowly and then with increasing rapidity, until the sound comes as a steady, pulsating roar. The display of the peacock, in which the long, ornamented upper tail-coverts (mistaken by many for the tail, which is short, stiff and dull in colour, entirely concealed beneath the longer feathers) are erected and fully spread, to be shaken finally with a dry rattle as the male faces the apparently indifferent female, is another well-known example of activity on the part of the male alone.

The great crested grebe has a complicated courtship-display in which both sexes participate. A pair approach, facing one another with head wagging from side to side, then raise one wing and preen the feathers beneath, an action varied in many ways to culminate finally in a weird dance in which the pair rise erect, treading water, and remain bolt upright with breasts nearly touching for a brief space.

In some species of albatross mutual courtship-displays have progressed to a point where they have far exceeded mere mating antics, and have become social customs that continue through a period of months, beginning with the arrival of the birds on the breeding grounds, and continuing until the young are grown. In the Laysan albatross (*Diomedea immutabilis*) of the islands west of Hawaii, the display begins with two birds approaching with quick bows, shaking their heads rapidly from side to side, raising the wing to preen the feathers beneath and finally throwing the head and neck fully erect, with the bill pointing perpendicularly to the sky, while both birds emit a hollow groan. This action is of daily occurrence when the birds are on land, from October to May, and is participated in by mates or neighbours.

As an example of the third type of display there may be mentioned the courtship of the phalaropes, in which the female has brighter plumage than the male and takes much of the initiative. In Wilson's phalarope (*Phalaropus tricolor*) both birds bow and nod, but in the culmination of this action the male flees with one, or sometimes two, females in close pursuit.

The site for the nest that is to contain the eggs is sometimes chosen by the female, sometimes indicated by the male, though the female may exhibit certain supposed prerogatives of her sex in such matters by modifying considerably the original plans proposed by her mate. The male house sparrow (*Passer domesticus*) when it chooses to nest in a cavity selects some suitable hollow, and rests beside the entrance, calling and chattering until a female comes to inspect the premises. If these appear suitable, nest construction may proceed. With species that nest in trees or bushes, or on the ground, where there is greater latitude of site, various locations may be examined before definite selection is made, both male and female apparently exhibiting directive impulse in choice. When suitable sites are numerous it is probable that final selection comes frequently through the chance that directs the placing of the first nesting-material when the courtship shall have proceeded to the point of actual nest construction. In some instances, where numerous sites all exactly alike are available, as where barn swallows (*Hirundo rustica erythrogaster*) make their nests of mud on rafters of a building, there is often confusion, so that birds may carry pellets of mud to a dozen rafters until one of the several foundations assumes more importance in their eyes than the others and a nest is brought to completion. In such species as the ruby-throated hummingbird (*Archilochus colubris*) and prairie hen (*Tympanuchus americanus*), where mating takes place at a point away from the nest and the male does not visit the nest-site, selection of a suitable spot rests entirely with the female.

With most birds mating is temporary, and may be for the period of a single brood, or, where two or more families are reared, for one nesting season. Some interesting information has been secured on this subject through marking birds with numbered bands which serve to distinguish such individuals from others of their kind. In these studies one male house wren (*Troglodytes aëdon*) was found mated with three different females in three successive years, and this same individual mated with two different mates for first and second broods during one season. Another wren mated with one companion for one brood, and in the following year took a new mate, with which it was found in the year succeeding. This shifting in the mating relation is not because of the death of one of the birds.

Though the majority of birds associate in pairs only during the nesting season there are some exceptions to this. The white-breasted nuthatch (*Sitta carolinensis*) of North America is found so invariably in pairs that when one appears alone the assumption is that something has killed its mate. Cardinals (*Richmondena cardinalis*) also may be found in pairs throughout the year. It is commonly stated that some birds, as eagles, mate for life, but this remains definitely to be proven.

Polygamy is practised by numbers of birds, particularly among the pheasant-like species. The males of the capercaillie (*Tetrao urogallus*), black grouse (*Lyrurus tetrix*) and wild turkey (*Meleagris gallopavo*) regularly take several mates, though the bobwhite (*Colinus virginianus*), a related species, is monogamous. Polyandry has been alleged for a number of species but needs verification as to regular occurrence since one of the forms concerned, the cowbird (*Molothrus ater*), where the female has been said to mate with several males, has been found to pair as regularly as is normal in small birds.

Nests.—The nests of birds (*see* NEST) exhibit a wide range in form and many have wonderful features.

The skimmer (*Rynchops nigra*) and the least tern (*Sterna antillarum*) excavate a slight hollow in sand or gravel to contain the eggs. The American avocet (*Recurvirostra americana*) may line a slight depression near the water's edge with a few bits of weed stem, and there deposit its four eggs. Subsequently, should the waters increase in freshet the avocet hustles about gathering grass, bits of wood, feathers, small bones and weeds to raise its treasures above the flood, so that where necessity arose, these birds have been known to erect piles of rubbish a foot in height. If the waters subsequently subside, these elevated nests become conspicuous structures but are not removed.

Some ground-nesting birds regularly conceal their eggs in holes. The Manx shearwater (*Puffinus puffinus*) digs burrows in loose soil and makes its nest at the end of the tunnel. There may be variation in method in one species, however, as the wedge-tailed shearwater (*Puffinus pacificus cuneatus*) of the Pacific Islands

ordinarily excavates a hole for nesting, but on rocky islands, where there is little soil, may deposit its egg on the ground, under bushes, or even in the open. The little auk or dovekie (*Plautus alle*) searches out a crevice or shelter beneath boulders, often on talus slopes where rock fragments are piled in great confusion. The belted kingfisher (*Megaceryle alcyon*) digs a tunnel on the face of a steep bank and lays its eggs at the end, gradually building up a mass of fish bones from regurgitated pellets for a nest.

Concealment is sought also by some tree-nesting birds. The scops owl (*Otus scops*) of Europe and the screech owl (*Otus asio*) of North America seek hollows in trees, where the eggs are placed without nest lining of any kind. Woodpeckers excavate special chambers in the trunks of trees, placing their eggs on an accumulation of chips at the bottom. Though dead trunks are usually chosen, the yellow-bellied woodpecker (*Sphyrapicus varius*) frequently drills its home in a living hardwood tree, and the Puerto Rican woodpecker (*Melanerpes portoricensis*) may nest in a living palm trunk.

Nests of many herons, *e.g.*, the night heron (*Nycticorax nycticorax*), are placed in trees, and are flat structures of twigs and sticks that form a mere platform, so loosely built that the eggs may often be seen from below. Among larger nests there is every variation from this type to that of the osprey (*Pandion haliaetus*) to which material may be added year after year until the mass is 8 or 10 ft. in diameter and makes a cartload in bulk.

Among smaller birds, the tree nest is usually a simple cup that has a foundation of rough material on which the nest proper of finer material rests; the lining is made of soft substances, as rootlets or plant downs. The blackbird (*Turdus merula*) and the American robin (*Turdus migratorius*) line their nests with cups of mud, within which are placed soft grasses. Many birds place nests of grasses and rootlets under herbage or in thickets on the ground. For protection, many tree-nesting birds build homes with arched tops that wholly conceal the eggs. There is a great group of birds in South America, the so-called tracheophones, many of whose species have this habit. Conspicuous among them in the Argentine is the leñatero, or firewood-gatherer (*Anumbius annumbi*), that gathers a quantity of thorny twigs to form a spherical mass, within which is placed the nest proper, reached by a runway, the whole so firmly constructed that the eggs inside may be reached only with difficulty. These nests are durable and last for several years, until the materials composing them decay. The ovenbirds (*Furnarius*) in this group construct rounded masses of mud, with an entrance at one side, the walls being an inch or more in thickness, and so built that they will withstand the beating of heavy rains without damage.

Many of the troupial family (*Icteridae*) make purselike nests that are suspended in the tops of trees. The nest of the oropendola (*Gymnostinops montezuma*) of Central America may be five feet in length, suspended by the upper end, below which is located the entrance which leads through a long, constricted neck to the expanded lower part, where the nest proper is placed. The oropendola nests in colonies, but nests of the orioles, as the Baltimore oriole (*Icterus galbula*) which also constructs a purse-shaped nest from 8 to 10 in. in length, are found alone. The nests of the social weaver finches of southern Africa are among the most remarkable structures known in the bird world. These birds are gregarious and, in company, accumulate masses of grass in trees to form a roof, under which each pair of birds has its separate cubicle, lined warmly with feathers. From 20 to 300 pairs may inhabit a single structure, which grows in size as it is inhabited year after year, until it may contain several wagonloads of material.

Among other curious nests there may be mentioned those of the edible-nest swiftlets of the Indian, Australian and Southwest Pacific areas, that are cupped platforms, composed of a coagulated mucus secreted by the mouth-glands of the birds, placed on the walls of caves. These are gathered commercially and form the basis for a soup highly prized by the Chinese. The American chimney swift (*Chaetura pelagica*) makes a nest of twigs, cemented together by mucus from the mouth, to form a tiny basket. In early times these nests were placed on the inside of hollow tree trunks, but with the advent of the Caucasian race and the building of houses, hollow trees have been forsaken for chimneys.

Nest-building with most birds usually seems to be the duty of the female. The male may assist by bringing material and may lay it on the nest, but it is mainly arranged by the female. In many species the entire work devolves upon the female.

EGGS

In birds, as in all other vertebrates, the gonads are paired organs on the dorsal wall of the body-cavity. In most birds the right ovary disappears early in life, leaving only the left to grow and mature. This rule, though usual, is not invariable, since in many hawks, particularly the harriers (*Circus*), and the small bird-eating forms (*Accipiter*) usually, but not invariably, we find both ovaries present and functional. The ovum, or yolk, in birds is a relatively enormous cell which passes from the ovary into the mouth of a convoluted tube, the oviduct. As the yolk moves down the oviduct it receives first a deposit of gelatinous albumen, the "white," next a membranous sheath and then is enclosed in a hard, calcareous shell, and is deposited as an egg (*q.v.*).

Eggs are ordinarily oval in shape, though this is not invariable, since the eggs of swifts are usually elliptical, and those of owls are nearly round. Eggs of birds that breed on rock ledges without constructing nests are much pointed, which allows them to roll about in a relatively small circle and so lessens the danger of a fall over the edge. Eggs of many shore birds, which are relatively large in relation to the size of the birds, are also strongly pointed, which permits them to pack closely with the pointed ends toward the centre, thus bringing the whole into a compass that permits the parent to cover them.

Eggs of owls, kingfishers and woodpeckers, which are laid usually in holes or cavities (though some owls occupy open nests) are white, and whitish eggs are found in grebes, albatrosses and petrels. Most eggs have, however, a coloured shell, or spots and blotches of colour spread over a lighter background. Where there is a pattern of markings present there is usually a wreath of heavy colour about the large end of the eggs. Most herons' eggs are pale blue or bluish-green, and plain green or blue eggs are found in various perching birds. The tinamous of the new world, a primitive group, have very striking eggs, with smooth and highly polished shells, varying from green or pink to deep brown, their lustre suggesting porcelain.

The eggshells are penetrated by pores which usually can not be seen, except under a lens, but that in some eggs, as those of the ostrich, are easily visible to the unaided eye. Evaporation takes place through these openings, so that the egg loses steadily in weight during the incubation period.

The number of eggs produced annually varies widely in different groups, being adjusted to the requirements of each species, to enable maintenance of its normal numbers. The migratory species that covers a considerable range encounters more dangers than one that is sedentary and, therefore, must produce more of its kind. This statement, however, has many exceptions. Migratory wild ducks lay from 5 to 12 eggs, while the bobwhite, which is sedentary, may have as many as 21, though usually not more than a dozen. Among small birds, on the average more eggs are deposited annually by the migratory species of the temperate zones than by the sedentary forms of the tropics. On the other hand, the nonmigratory titmice and wrens lay many more eggs than the migratory warblers (*Sylviidae*). Most perching birds of temperate regions have from three to five eggs, rarely six, in a setting, but may nest two or three times each season. Most sandpipers deposit four eggs, though in some the number is reduced to three. Many gulls, hummingbirds, loons and some species of pigeons lay two eggs regularly. Other kinds of pigeons, with auks, petrels and albatrosses, lay but one egg. Boobies lay two eggs, but never seem to rear more than one young.

Adjustment of birds to their environment as regards the number of eggs deposited, to ensure continuance of each species, was made before the rise of man, who has been an active factor in the life of the earth for a relatively brief period compared to other animals. In some cases, where man has kept in check enemies of

birds, these species have increased. In other instances, where man has been an active enemy, he has brought about reduction in numbers or actual extermination, because the birds concerned had become adjusted to a certain annual drain on their numbers from natural enemies and were unable to change to counteract added destruction by man. The great auk laid only one egg, and since it nested in colonies was quickly exterminated. The passenger pigeon of North America, which existed in colonial days in innumerable hosts, also produced but one egg at a setting, which did not enable it to withstand the drain of hunting, so that it has become extinct. Usually, only those birds which rear a number of young each year can be maintained as game, and these must have protective regulation to enable them to hold their own.

Incubation.—After the egg is deposited it requires a certain definite temperature to develop to the point of hatching. This is normally accomplished by incubation on the part of one of the parents, usually the female, a period during which the bird remains closely on the nest, except for brief intervals required for a hasty search for food. The eggs are warmed by being brought into close contact with the breast and abdomen of the brooding bird, there being usually a sloughing of down and other feathers over a part of this area, to permit close contact between the skin and the eggs, and at the same time an increase in the blood supply to the skin, to bring a more even heat to bear. The actual degree of heat required to develop the embryo in the egg is known for only a few forms of birds. In the case of the domestic fowl the average incubation temperature is about 103° F. In charts published by Baldwin and Kendeigh, showing by use of a thermocouple fluctuating temperature in the nest of a house wren (*Troglodytes aëdon*), the incubating temperature is shown to vary from 39° to 41° C., or 102° to 106° F., the average being about 104° F.

Though, ordinarily, care of the eggs involves their being heated from the body of the incubating bird, in species that nest in the open, in warm climates, where the sun is torrid, brooding may be required to shade the eggs from too powerful sunrays. The body of the bird here acts as a shelter and an equalizer of heat.

Though incubation falls ordinarily to the lot of the female, there are many species in which both sexes alternate in this duty. This is true in the ostrich, various auklets, herons, grebes, petrels, etc. The male rose-breasted grosbeak (*Pheucticus ludovicianus*) broods devotedly, though in this case his action would seem disadvantageous, as his plumage is strikingly variegated with black and white, and the rose-red spot on his breast often shows above the rim of the nest, while his mate is inconspicuous in a brown, streaked dress. In the phalaropes, the bustard quails (*Turnix*), the emu and the rhea the male alone incubates, the female taking no part in this duty. It is believed that this also obtains in some other shore birds.

The megapodes or mound-builders (*Megapodiidae*), found from the Nicobars and Philippine Islands to Australia, carry on no incubation whatever. For example, the scrub fowl (*Megapodius reinwardt*), of Northern Territory and Queensland in Australia, scrapes together a mound of sand, earth, sticks and other debris, to which a small amount of vegetation is added, during the wet season. The mound may be used for a number of consecutive seasons; and mounds 14 ft. in height and 35 ft. in diameter have been discovered. The eggs of one pair of birds are buried in the top of such a mound, and, through heat generated by decomposition of the included vegetation, are maintained at an even temperature of 95° F. The nesting activities of these curious birds are strongly reminiscent of the breeding habits of the reptilian group, from which the class of birds as a whole is descended.

The period of incubation varies greatly in different groups, in general, being longer in large birds. The period may be shortened slightly by slight increase in incubation temperature or prolonged somewhat by irregular attention on the part of the parent. The incubation period of the emu is said to range from 56 to 63 days, that of the ostrich is reported as 42 days, the domestic mallard requires 4 weeks and the domestic fowl 3 weeks. Most small perching birds require from 12 to 14 days, with magpies and jays running from 16 to 18 days. One of the shortest incubation periods known is that of the American cowbird (*Molothrus ater*), whose eggs hatch after 10½ days' incubation. The ruddy quail-dove also is given as 10 days.

In the gallinaceous birds; *e.g.*, the domestic fowl, and many other species, the nest is used merely to house and incubate the eggs and the young, which are born covered with down and follow the mother in search of food as soon as their plumage is dry. In some mound birds the young are hatched with developed wing quills, so that they are able to fly within half-an-hour of hatching. In most tree-nesting species the young undergo a shorter period of development in the egg, and consequently must remain in the nest under close parental care for a period after hatching. The nest is thus a home during early juvenile development. Food is sought by the parents and brought to the young, and what guard may be possible is maintained against destructive enemies. In hole-nesting species like the hoopoes and woodpeckers there is indifference to nest sanitation, since immunity against dangerous bacteria that multiply actively when heat and moisture are available has apparently been developed. Such nests become extremely foul as the period of occupancy progresses. Hawks, herons and numerous others, even when very young, instinctively void their excrement beyond the nest, so that such unsanitary condition is obviated. In most of the smaller perching birds the excrement of the young is of such a consistency that it maintains a globular form and is removed from the nest by the parent. In a few finches, as the American goldfinch and crossbills, the excreta are voided by the young about the margin of the nest and are not removed.

In most birds the young remain with the parents for a time after leaving the nest, and gradually become self-reliant, so that they procure their own food. At this stage family parties usually separate as the young drift away from their parents, or the adults tire of importunate begging for food on the part of progeny able to procure their own sustenance, and so either drive the young away or themselves leave. When the young learn early to search for food, they may remain in bands with their parents.

Parasitism.—Breeding parasitism is found in several groups of birds in which no nest is built, the eggs being deposited with those of other birds and left entirely to the foster parent for care. The European cuckoo (*Cuculus canorus*) has long been known to have such habits. The female places a single egg in the nest of some bird, usually a species of small size, ordinarily choosing a nest in which the eggs are fresh, and removing one of the rightful set when leaving her own (*see* CUCKOO). Although about 100 species of birds have been recorded as parasitized, ordinarily each female cuckoo places her eggs in the nests of one particular species of bird. Each female cuckoo is supposed to lay from 5 to 16 eggs during the season. There is argument as to whether the cuckoo deposits her egg directly in the nest of the fosterer or whether she extrudes the egg elsewhere and carries it in her throat to the nest chosen. The former is certainly the more usual. An egg of the foster parent is almost invariably removed and eaten by the cuckoo after she has deposited her own. The process of placing the egg requires only a few seconds, and then the bird leaves at once, which renders definite observation difficult. The young cuckoo's back, hypersensitive to touch, has a spasmodic reaction when it comes in contact with objects other than the nest; aided by a curious depression on the back, the parasite casts out the rightful young, or the eggs until finally it occupies the nest alone.

Similar parasitic habits are known for a number of other cuckoos in other parts of the world. Stuart Baker, in discussing parasitism in Indian cuckoos, shows that a number are parasitic on one species or group of species of birds, and that the cuckoo's egg is specialized to resemble the foster parent's rather closely. In some cases one cuckoo may have widely different eggs in different parts of its range, as the hawk cuckoo (*Cuculus sparverioïdes*), which, when it parasitizes the streaked spider hunter (*Arachnothera magna*), lays a dark olive-brown egg like that of the bird parasitized, but that elsewhere foists on the laughing thrushes or allied species a bright blue egg like that of its dupes.

Some of the American cowbirds are also parasitic. The common North American cowbird (*Molothrus ater*) has developed no particular resemblance in egg colour to the egg of the fosterer, except

that many of its dupes lay spotted eggs like its own. In South America the bay-winged cowbird (*Molothrus badius*) cares for its own eggs in a normal manner, but is parasitized by a related species, the screaming cowbird (*Molothrus rufo-axillaris*), which uses this species alone as foster parent. Parasitism is also known in the rice grackles (*Psomocolax orizivorus*) which lay in the nests of related oriole-like birds. Certain species of weaverbirds (*Ploceidae*) and the honey guides (*Indicatoridae*) of Africa also parasitize other birds. The origin of such habits is obscure.

POST-BREEDING LIFE

The period of reproduction is the most active part of the annual life-cycle of the bird, from a biological standpoint, since it brings in play instincts and activities different and more complex from those apparent during the remainder of the year. Reproductive activity reaches its climax with the maturity of the young. With these on the wing the individual pair have done their utmost in the perpetuation of their kind, and there ensue a number of months of more restful life, with search for food and escape from enemies as the principal activities. For many species there is immediately a period of moult to renew the feathers, a period during which birds are quiet and sluggish, often seeking haunts where they will be disturbed as little as possible. With the drain on vitality brought by feather production at an end, there comes a time of greater activity, when old and young seem to attain greater vitality.

Moult.—The close of the breeding season finds adult birds with worn feathers, so that most species immediately undergo a moult, during which the old feathers are dropped and new ones are grown. The process is one that, in totality, requires more than a month to complete and progresses in regular routine, varying in sequence over the body in the different orders. In most species the feathers of the wing are shed and renewed one or two at a time, so that the bird still retains the power of flight. Ducks, geese, flamingos, cranes, rails and grebes drop all the wing and tail feathers in a very short time, so that they become flightless for several weeks until new feathers are grown. Penguins shed their feathers in patches, almost as a lizard drops its old skin. The epidermis of the tarsus and feet is sloughed during the moult, and any ornamental coverings of the beak are dropped at the same time.

Young birds have a first plumage, grown during their period of development, that is replaced by a post-juvenile dress of feathers that comes when they are fully grown and able to care for themselves. In most, the flight feathers remain until the following year, but in some, as the house sparrow (*Passer domesticus*), the wing and tail quills are also completely renewed at this first moult.

In most adult birds the moult comes immediately after the close of the breeding season, and in temperate regions occurs in late summer. The birds are thus again in full dress when the time for migration arrives, or, if resident, by the approach of cold weather. Swallows, many shore birds and hawks moult during the winter, the two former groups undergoing this process in the winter home after migration.

Most birds have one complete moult annually; but in many, particularly among the perching birds, there is another, partial or complete, through which the bird acquires nuptial plumes. In the bobolink (*Dolichonyx orizivorus*) and the whinchat (*Saxicola rubetra*), for example, the body plumage is completely changed in late winter and early spring. Many of the sparrow family, as the cirl bunting (*Emberiza cirlus*) and the Harris's sparrow (*Zonotrichia querula*), have a partial moult of the feathers about the head that produces new plumes for the breeding dress.

Change in colour is not necessarily accompanied by moult, as often the tip of a feather may be one colour and the middle portion another. In the throat of the male house sparrow, for example, in autumn and early winter the black throat is obscured by greyish feather tips. As spring arrives the gray tips wear away, so that the black is fully revealed. The most striking change of this type is found in the snow bunting (*Plectrophenax nivalis*), which is white or light brown above in autumn and winter, but through sloughing of the feather tips becomes entirely black on the back in spring.

MIGRATION

Aristotle (384–322 B.C.), the first to discourse connectedly on bird migration (*see* BIRDS, MIGRATION OF), tells in his writings that the crane flies from the steppes of Scythia to the marshlands at the source of the Nile, south of Egypt. He noted migration also in the swan, land rail, lesser goose, quail, rock dove and turtle dove, though he reports that of the last three a few may linger through the winter in protected localities. The cuckoo disappeared with the rising of the dog star in July. Pliny, in his *Natural History,* repeats much that had been said by Aristotle. adding that the European blackbird, starlings and thrushes pass to neighbouring countries, while storks and cranes travel to a great distance. There are scattered references to migration in the writings of the middle ages, Olaus Magnus, in 1555, speaking of the migrations of swallows, and Francis Willughby, in 1678, mentioning various migratory birds. In the succeeding century Gilbert White, Thomas Pennant and George Edwards kept regular records of the arrival and departure of birds. Interest in the subject was considerable by the opening of the 19th century, and from that time forward the number of observers and the mass of published information on migration have increased yearly.

Superstitious Beliefs.—Though the migrations of larger birds were understood, since these travelled openly across the spring and autumn skies, the movement of smaller species, that appeared or disappeared under cover of night, so that they were present one day and gone the next, or were present suddenly after an absence of several months, was the basis of considerable superstitious belief. It was thought that the smaller species were too weak to travel far, so that, in 1740, J. G. Gmelin was told by the Tatars of Krasnojarsk that each crane carried a corn crake on its back in its journeys. In southern Europe the peasantry believe today that small birds congregate on the shores of the Mediterranean, and as opportunity offers flutter on the backs of storks and cranes who carry them across to Africa.

Somewhat more unusual is a belief promulgated in an anonymous tract published in London in 1703 "By a person of Learning and Piety," entitled in part "An Essay Towards the Probable Solution of this Question. Whence come the Stork and the Turtle. the Crane, and the Swallow, when they Know and Observe the Appointed Time of their Coming." The author announces a belief that migratory birds travel to the moon, where they pass the winter, the journey in either direction requiring 60 days to compass, during which the author (who, according to Hugh Gladstone, was Charles Moreton, a minister who in late life moved to New England), informs us that they required no food, since they travelled in a rarefied ether.

Another superstition centring around migration has been the supposed hibernation on the part of some birds, a belief that dates back to early times and has been prevalent both in Europe and America. Aristotle attributed hibernation to the swallow and various other birds, saying that some individuals became torpid and so passed the winter in the shelter of caves or hollow trees in a state of suspended animation. In later years hibernation was used mainly to explain the disappearance of swifts, swallows and the sora rail. Many and detailed have been the arguments over this matter, and more than 200 papers have been written dealing with supposed cases of hibernation. It was related that the sora rail abounded in its favourite marshes, until, overnight, the birds turned into frogs, or sank in the mud, to remain until the following spring. Naturalists with great detail describe how swallows gathered on reeds growing in water until their combined weights bent down these slender supports and the birds were submerged in the water. Those to whom this theory did not appeal stated that swallows and swifts hibernated in hollow trees and clefts in rocks, and the finding of birds in such situations in winter was described in great detail in a number of instances, all, however, under some misunderstanding of the circumstances. In short, though hibernation, or its correlate aestivation, is common among mammals, reptiles, amphibians and even in fishes, it has never been proved among birds. The frequent coupling of this superstition with swallows may be explained, perhaps, by the fact that these birds in autumn regularly roost at night in marshes, and that

during storms many perish to fall into the water and sink into the mud, never, however, to revive.

Among other superstitious beliefs mention may be made also of a transmutation theory prevalent among early writers, who supposed that at the approach of winter a bird might be transformed into another species, to remain thus until spring, when it resumed its proper form. Apparently this was first suggested by Aristotle, who held that the redbreast or robin (of Europe) changed to the redstart. The confusion resulted, apparently, from similarity of form and difference of plumage in two related species, where one disappeared in southward migration about the time that another arrived from northern regions, thus lending colour to a transmutation argument.

Theories of Origin.—An explanation of migrational movement has been that of seasonal change in food supply. According to this belief, with the approach of winter in areas remote from the equator, there is failure of the food supply that causes birds to travel, and as the food supplies remain more constant toward the tropics, birds move in that direction. When, with the approach of spring, the instinct for reproduction becomes paramount, since the food supplies of the broad equatorial area are not sufficient to support the great host of young birds that will appear, the adults move out again to their summer homes in temperate or boreal regions, where they rear their families. It may be argued against this that the tropical belt supports the migratory hosts when they have become grown, so that it would seem that these same individuals might obtain sustenance there while in younger stages.

An allied theory contends that migration is controlled by cold, from which birds retreat in autumn. Under this hypothesis some have held that birds originated in the north, were driven south by the advance of ice in the Pleistocene, and have returned to the north with the coming of milder climate. Each year now they retreat before the breath of approaching winter, while each spring a love of birthplace calls them to their natal homes. It must be noted that many birds retreat south early in the season, long before there is climatic necessity for their movement. This, with similar facts, has given rise to the theory that all species of birds have had their origin in the south, and through a natural struggle among individuals have spread to the north, especially for the period when each pair must be bound to a restricted territory for its breeding ground.

A somewhat different theory is that of phototropism, which holds that birds move toward the region of greatest light, this bringing a natural ebb and flow of bird life with the changing seasons as the sun moves north and south across the equator. It is true that the course of migration, in general, follows the advance and retreat of the sun, but it would seem that it is the changing season and not the change in intensity in light itself that affects our bird life. Through phototropism we may not, for example, explain the migrations of nightjars, which are nocturnal, and which, therefore, find in darkness the period of their activity. Such birds should find their optimum conditions of life in the equatorial regions, where the hours of the day are divided between daylight and darkness. The nightjar and whippoorwill, to give two well-known examples, travel north to breed, and in June in their northern ranges have their hours of activity greatly curtailed through the lengthened period of daylight. Recent studies based on considerable experimentation show that the onset of migration is physiologically controlled by the relative length of day and night, as is known to be the case with the flowering of plants. In other words, it is correlated with the effect of light. The factors appear complex but when they are better understood it seems probable that through them we will have understanding of the method of migration as it exists, if not of its origin.

The main difficulty with these and a number of other theories that have been promulgated in connection with migration is that they attempt to explain this great and impelling semiannual movement by some single factor. When we consider that the known history of the bird in its evolutionary development, from present knowledge goes back through an enormous stretch of time, so vast that it may be noted in figures but is beyond human comprehension, to the fossil species known as *Archaeopteryx* and *Archaeornis* of the Jurassic period, it must be recognized that our present-day species have had their instincts and habits moulded by many factors, so that it seems reasonable to consider that such a widespread phenomenon as migration may be because of a complex association of a number of powerful causes, some of which may have affected one species and some another, but no one of which may serve to explain the entire activity as it exists at present.

We may believe, therefore, that the underlying basis of migration is founded on a combination of a number of causes, and we may look upon the present migratory instinct as an outgrowth of all the complex circumstances that have affected birds during their entire evolution, though it seems evident that the actual routes followed by migratory birds, at least in the northern hemisphere, have been shaped during the climatic changes of the Pleistocene.

During breeding period the bird is restricted closely to the region in which the nest is located, and though some young are free to move about when recently hatched, the parents are, as a rule, confined to one neighbourhood until their offspring may be old enough to require no further care. This close confinement is seen easily in the smaller perching birds that are held within a limited range until the young are finally on the wing. When the young are grown the adults may linger to rear other broods, but the young, driven often by antagonism of erstwhile attentive parents, wander away, borne by their newly developed wings, and though they may not go far, do not usually remain for long in the immediate vicinity of the nest. This is one type of wandering in its simplest form. Somewhat more complex is the condition found in some parts of Australia, where prolonged droughts occur, vegetation is not developed and the majority of birds disappear. With the incidence of rains the country again becomes green and birds return. Though both kinds of movement that have been described may appear as vagrancy, yet such impulses need only to become synchronized with seasonal climatic change to become true migration.

Tropical regions offer interesting data in this connection, since, though hundreds of birds found in these areas are strictly sedentary, there are some that shift about with changing conditions. Climatic variation within the tropics is confined mainly to a cycle, in which periods of relatively little precipitation alternate with those of heavy rains. There is thus a seasonal shift that is influenced by changes in the vegetation. Some species of tree or vine come into flower or fruit and immediately there appear tanagers, honey eaters and other birds hitherto absent to live upon the newly available food.

It is idle to suppose all birds have arisen within either tropical or temperate areas. Birds, as a group, have been in existence for many million years, and during all that period there has been constant unceasing competition between individuals. In virile species individuals have been produced in abundance, and many have necessarily been forced out into new range. Some have reacted to new conditions, or have become modified through some inherent quality, so that they have been changed so greatly that they have finally become species apart from the parent stock, and have thus set up their own *loci* for subsequent radiation. The complexity of overlapping ranges under such conditions is easily apparent.

HOW MIGRATION PROCEEDS

Some students have indicated that the spring and fall migrations correspond to advance to the breeding station and subsequent retreat therefrom, and indicate correctly that the stimulus for this may be a hormone arising from physiological change in the gonads. This, however, is merely an activating principle for migration as it exists at the moment, and may not be considered the cause through which migration itself has originated.

Briefly, migration may be defined as advance and retreat, with fluctuation in conditions favourable to each species separately, which, as each form has its own reaction to its environment, has originated from varying causes. The origin of the present-day regular, seasonal movements is thus complex.

Methods of Migration.—Migration may take place by day or by night, according to the species. Geese, ducks, cranes and pelicans crossing the sky, flying abreast or in angular formation, are

accepted as portents of changing season throughout the world. Though seen regularly by day, these birds may also migrate by night, since we frequently hear the calls of geese and swans coming from darkened skies during the height of their movements. The smaller birds travel mainly by night, and descend on us in hordes, so that frequently we go out in early morning to find fields and hedgerows crowded with songsters that were absent the previous evening. During the proper season, when a full moon rides the sky in evening, it is possible to detect the forms of these nocturnal travellers silhouetted against the illuminated disk of light as they pass far above the earth, and occasionally to recognize a feathered friend by some peculiarity of form or wing movement. Many such observations have been made through large telescopes, and birds may be seen occasionally against the moon through ordinary field glasses. It is probable that timid wrens, warblers and sparrows, that live ordinarily under shelter, feel greater safety in prolonged flights under the protecting cover of darkness. Kingbirds, robins, bluebirds, bluejays and many others, however, regularly fly by day.

The matter of procurement of food may be as great a factor as timidity in inducing nocturnal flight. Digestion in birds is rapid, so that food must be obtained at regular intervals to maintain the activity especially characteristic of smaller species, whose tiny bodies have necessarily smaller reserves of energy than their larger brethren. Stomachs of small birds killed at night by striking lights or other obstructions are nearly always entirely empty, which, though an entirely natural thing, in some cases has given rise to belief that the individuals in question were in the throes of starvation. If tiny migrants flew long distances by day they would arrive at some distant destination with empty stomachs and depleted energies, perhaps almost exhausted, and because of darkness would not be able to procure food until the following morning. Such circumstances would lead to delay in further flights through need for recuperation or, if accompanied by cold or storm, might prove fatal because of lowered vitality. By arrival at daybreak it is possible for migrants to rest for a time and then search for food, and so to recuperate that they may continue the following evening if desired. At the same time there is often detected among these smaller species an indication of continuation of migratory flight by day, since in feeding they frequently tend to move in the general direction toward which the seasonal flight trends. It was thought formerly that migrants flew at great altitudes above the earth, there being a somewhat hazy notion that rarefied atmosphere in some uncertain way facilitated flight. Modern observations from aircraft show, however, that this belief is unfounded, and that the bulk of migrant birds travel at less than 3,000 ft. above the earth. It is unusual to meet with birds above 5,000 ft., though exceptionally aviators have recorded shore birds at 10,000 and 12,000 feet. In many instances birds pass at moderate altitudes, particularly above the sea, where they may barely clear the waves. At night, the calls of migrants may be often heard, apparently only short distances above the trees.

There has been much discussion of the method by which birds direct their courses in flights to distant lands, without arrival at definite explanation. Memory of routes previously travelled, some magnetic sense, courses laid by the positions of the heavenly bodies, as a mariner directs his navigation, the direction of regular winds, telepathy and hereditary memory have all had their champions. It may be said that there appears great probability that young birds of the season, on occasion, migrate southward without the guidance of others that have previously made the journey, that sea birds return across apparently trackless oceans to remote islands where they nest, and that sea birds have returned to their breeding stations when removed forcibly to waters that they do not ordinarily frequent. This may, perhaps, be explained in the somewhat general terms, by supposition, that the birds are directed by some special sense of direction, but must be regarded at present as something of which there is no definite explanation in spite of theories that have been advanced.

One of the most interesting facts connected with migration is the almost unfailing regularity that accompanies the movements of birds in the temperate regions. Through records kept over a long period of years, the average dates of arrival in spring of the common birds are now known, and it is found that they appear with almost uncanny regularity, often on the average day and always within a range of a few days earlier or later. Among small birds the seedeaters generally migrate earlier in spring and later in autumn than insect eaters since their food is available regardless of colder weather, unless covered by snow. The first arrivals in spring or fall are usually few, and it may be days or weeks before the mass of individuals appear.

The length of the journeys made by individual birds varies greatly. Inhabitants of high mountains, in a flight of a mile or two, descend to some sheltered valley, where they may spend the winter in comfort, or the migration flight may entail a movement to a great distance, as from central Europe to southern Africa. The arctic tern is supposed to have the longest migration route known, since it nests in the far north and spends the northern winter near the shores of the Antarctic continent, with 11,000 mi. in an air line separating its northern and southern homes. Incidentally, this tern probably enjoys longer hours of daylight than any other living creature, since it lives under the midnight sun in both northern and southern hemispheres, and only in its travels through the equatorial belt does it meet extended periods of darkness. There are numerous shore birds, such as the American golden plover, that nest in the arctic and spend the northern winter on the plains of Argentina. Many birds nest in Canada or in the northern United States and winter in the Gulf states, Mexico, Central America, the West Indies or northern South America. Likewise, many pass from northern Europe to Africa, some going as far as Cape Colony.

Through prolonged journeys birds encounter constant perils and dangers, so that many are destroyed. Storms, unfamiliar coverts, with consequent exposure to the attacks of enemies, and wandering from the direct course in crossing broad reaches of water annually exact a toll of unknown thousands of individuals, as has been indicated in a previous section. To enable maintenance of their proper number migratory species, therefore, are required to produce a sufficient number of young to permit this toll, and at the same time leave a pair to continue the species at the next breeding season. On the average, the migratory species of the north and south temperate zones produce from three to six eggs in each nesting, four or five being the rule, with from one to three families each season, while the more strictly resident form of the tropics may produce only two or three eggs and have only one nesting annually. In spite of apparent prolificness the more northern species do not increase inordinately. The song sparrow family, in August, at the close of the breeding season, if there has been no mortality, may have 10 or 14 individuals, depending upon whether 2 or 3 broods have been reared, yet by next spring does not show any appreciable increase in abundance; so that there has been a tremendous wastage in individual life during the migrations and the intervening winter.

In final consideration, it may be said that residents in Europe and North America are often prone to consider migration as something peculiar to birds breeding in the northern hemisphere. It must be noted, however, that in South America, southern Africa and Australia there are native species that, at the approach of the southern winter, travel north toward the equator, to return at the proper season to their breeding grounds. (*See* also BIRDS, MIGRATION OF.)

Until the beginning of the present century the study of migration was carried on by mass observation, under which records were kept of the first appearance for each species and of its subsequent fluctuations in abundance, the value of the records depending to a certain degree upon the skill and experience of the observer. Much valuable data has thus been assembled, and this method of study is still highly useful. As the next forward step in these studies, methods were developed in marking individual birds with numbered bands that have added greatly to knowledge of migration, since by this means it is possible to single out the individual bird from the great army of his fellows, and to learn something of the separate flights that make up this mass movement. (*See* BIRD BANDING.)

SONGS AND CALLS

The voice in mammals, including man, is produced in the voice box, or larynx, in the upper part of the throat. The bird possesses a similar larynx; but its sounds and notes are formed in another voice box, the syrinx, at the lower end of the windpipe, where it divides to send a bronchial tube to either lung. The syrinx is composed of firm walls derived from the rings of the trachea, or in part from the bronchi, and has within delicate membranes whose tension is controlled by slender muscles. Air expelled forcibly over these membranes produces sound which may be of many kinds, according to the species concerned. The adult turkey vulture (*Cathartes aura*) and the brown pelican (*Pelecanus occidentalis*) have as their only note a sighing aspiration made by expelling the air unmodulated, though their young utter harsh calls in some variety, either in begging for food or in attempting to repel possible enemies. The voiceless condition in the adult is unusual. The rhea sends forth a booming call, ventriloquial in effect, that carries for long distances; the wedge-tailed shearwater utters a series of indescribable groans and shrieks, which combine with those of thousands of its kind to produce a vast volume of sound; the gull or tern calls in constant iteration with a note of harshest sound. In the highest groups of birds, among the oscines or songbirds, song has reached high development, and in many follows lines of human music sufficiently to give deep aesthetic pleasure. The male mockingbird (*Mimus polyglottos*) of America, is stirred by spring to a period of vocal utterance that includes a varied repertoire of utterances peculiar to his own expression, as well as notes borrowed from tuneful neighbours. In the height of the breeding season his efforts continue day and night in apparently ceaseless expression of virile energy. The nightingale (*Luscinia megarhyncha*) of Europe, a dweller of tangled copses, would be overlooked by many were it not for his impassioned outburst of song (which, contrary to popular belief, may be heard at all hours of day and night). The two just mentioned, with the addition of the hermit thrush and the skylark, are the songsters of greatest renown among English-speaking peoples.

A number of bird songs, even where they have variety of note, are frequently unpleasant to some human ears. Many complain of the doleful cadence of the cooing of mourning doves (*Zenaidura macroura*), or are unpleasantly affected by the harsh chatter of the house sparrow. The song of the plant cutter (*Phytotoma rutila*) of Argentina exactly resembles the creaking of two tree-limbs rubbing against one another in the wind. The song of the Henslow's sparrow (*Passerherbulus henslowii*) is a low double note barely audible at a hundred yards.

The song impulse is so predominant at the height of its period that it is given expression on the slightest disturbance. Birds awakened at night frequently sing for an instant as clearly as during the day, and song also may be used to express emotions of fear and anger.

Though modulated speech for the expression of abstract ideas may be peculiar to man, there is no question but that birds possess a rudimentary language in the sense that they use their calls to communicate with one another. A low call on the part of a parrot or paroquet at detection of a sound or sight that may denote danger will instantly cause the entire group of its companions to become motionless, or send them in screaming confusion into the air. The mother pheasant warns her young, who immediately hide and can not be found. The rooster, by rapid repetition of a certain note, calls the members of his harem to some supply of food. There are also cries of anger, and others that may be interpreted as conversational, that enable species of social habit to keep in touch with one another. Bird calls are often intelligible to other creatures, as the alarm call of a jay or plover will often startle deer or other game.

There are a number of birds that possess a strong imitative faculty which, in domesticated individuals, may be adapted to the mimicry of human sounds. Canaries and other finches may be taught to whistle a few notes of musical airs. The Amazon parrots are particularly adept at mimicry of the human voice, and similar ability is found in some macaws, paroquets and other parrots. Crows, jays and magpies also may learn to repeat a few words, as may starlings and mynahs. According to a widely current superstition the tongues of the latter birds must be split to enable them to articulate human speech, a belief for which there is no valid basis whatever, and which, when practised, imposes a needless cruelty. This curious belief may be based on the fact that the tongue of crows and jays is naturally bifid at the tip.

FLIGHT

The wing membranes of the ancient reptilian pterosaur (*see* PTERODACTYL) were supported by elongated finger bones, as are the wings of bats (though differently), but birds have developed another mechanism for flying, since the forelimb, including the hand, has long feathers projecting from its posterior margin that are extended to form a supporting surface, by which flight is accomplished (*see* also BIRDS). The hand is stiffened, being flexible only at the wrist, the number of hand and finger bones is reduced and those that remain are partly fused together. The wing thus developed folds against the sides, so that it causes no embarrassment when the bird is at rest or is walking or climbing, but at the same time may be extended instantly should need or desire for flight arise. It appears thus perfectly adapted for its purpose.

Methods in Flight.—Avian flight is accomplished, except when soaring, by strokes of the wings, which may be slow or fast according to circumstances or the custom of the bird. A certain momentum must be acquired before the bird actually moves through the air. From a level surface ordinarily this is accomplished by an initial spring, through which the flexed legs throw the body as though from a catapult. From an elevation, as from a cliff or the limb of a tree, a fall of a few inches or a few feet may occur before the bird is under way. Albatrosses take off from land facing the wind, running a few steps forward with beating wings and then spreading their pinions, to rise and sail gracefully away. Some aquatic birds with small wings and heavy bodies, as coots, diving ducks, grebes and loons, rush across the water surface with beating wings and alternately striking feet until they acquire sufficient momentum to carry them into the air. Surface-feeding ducks, on the contrary, spring directly into the air with one tremendous impulse that gives such impetus that they fly without appreciable pause. Grebes rise with difficulty except from the water. From a smooth, hard surface they can sometimes take off in flight, but in herbage they are unable to rise, since the slightest obstructions break their momentum.

There is a considerable group of birds which in their active moments are so constantly in the air that they may almost be termed aerial creatures. The swallows are an excellent example of these since they secure their entire supply of food in the air, and for hours on end circle and swing with tirelessly moving wings, only perching when their appetite is satisfied, for the purpose of rest at night, or at their nests.

Aerial existence of a stronger, more placid type, is exemplified by the great vultures and the larger hawks that circle and turn on broadly extended wings above the earth, frequently at great heights. Such birds may soar for hours with only an occasional stroke of the wings, since they use the force of rising or laterally moving air currents to maintain themselves, the only motion being a constant slight adjustment of the angle of the wings, particularly at the tips, and of the tail to secure the proper amount of upward thrust to enable them to maintain the desired altitude and at the same time move ahead. The turkey vulture (*Cathartes aura*), which uses a soaring flight constantly for its progress through the air, is seldom abroad on foggy days when the air is still, but on such occasions remains quietly in its roost. Many other birds soar merely for the pleasure that this occasions. Pelicans, cormorants, storks and screamers, to mention only a few, are seen wheeling for hours so high above the earth that they appear as mere specks in the sky, though these birds search for food near, or on, the surface of water or the ground. Soaring flight of a different kind is seen where gulls glide beside or over a vessel, holding steady position in one place for minutes at a time without movement of the wings. This is accomplished by utiliza-

tion of the steady air currents that are deflected from the surfaces of the boat at a constant angle.

Hawks and the other soaring birds mentioned which perform their flights relatively high in the air have wings wide in proportion to their length. Albatrosses and other sea birds that travel habitually near the surface of the water have long, narrow wings which when fully extended are more or less of equal width throughout their length. These birds progress by utilization of air currents induced by wind, and are most common in pelagic regions where there are regular winds, and are rare in regions of calm. Their flight is quick and subject to sudden turns, so that the method of progression differs somewhat from the smooth, spiralling turns that mark the soaring of hawks and vultures. As the larger petrel-like birds follow in the wake of ships they bank and turn rapidly with stiffly extended wings, frequently swinging so that the plane of the wings for a brief space is at right angles to the line of the horizon. It is common to see shearwaters caught in the trough of a wave fly rapidly to the crest and then scale with set wings down the succeeding moving slope of water.

Birds like magpies and ducks, which habitually fly long distances, travel with a steady beat of the wings that carries them in a smooth, direct line. Inhabitants of thickets and hedgerows, as sparrows and wrens, progress with a tilting flight in which the short, rounded wings move rapidly for a few quick strokes and then pause for a very brief instant, so that the flight is rapidly tilting, or irregular in a vertical plane. Another group of birds, as many woodpeckers, fly in long undulations with a regular rise, during which the wings are stroked rapidly, and a slow descent, during which they are closed and the bird progresses through a combination of its previous momentum and the pull of gravity.

Such ground-haunting birds as the grouse and quails regularly walk or run, and use their wings extensively only to carry them from danger. In these the wings move rapidly, so that flight is swift and is accompanied by a roaring sound. The rapid movement is maintained for a comparatively short distance when the bird drops to the ground to hide in cover. Flight at high speed is thus maintained for only a brief space. The tinamous (*Tinamidae*) of South and Central America, birds of grouselike appearance related to the rheas, like grouse, fly only when pressed. They rise violently and drive rapidly away for fair distances, but are reluctant to rise again, and when forced to fly a second or third time do so with some difficulty. They are so seldom in the air that in violent winds they can not easily control their direction and often alight so clumsily that they fall.

Ground-inhabiting birds that reside on islands where they have no regular persistent enemies, have little incentive to flight, with the result that wings become shortened and their movement weakened. In many instances, particularly among rails, this has resulted in species in which the power of flight is completely lost, and the wings, though they may beat rapidly as the bird runs, can not raise it from the ground. In some species now living loss of power of flight is now taking place. The Laysan teal (*Anas laysanensis*) is now in this process, so that, though an initial flight of about 100 yd. may be made, the birds are then exhausted and may sometimes be caught by hand.

Speed of Flight.—The speed that birds attain in flight, until comparatively recent years, has been a matter of uncertainty, in many cases subject to gross exaggerations. Most of these may be traced to H. Gätke, who in his otherwise admirable studies of migration on the island of Heligoland became seized with the hypothesis that birds perform most of their migration flight during the course of a single night. On this theory, he placed the migratory speed of the northern blue-throat at 180 to 240 mi. per hour, the hooded crow at 108 mi. and plovers and related species at 240 mi. per hour, or 4 mi. per minute. He believed that these tremendous speeds were possible through flight at great altitudes, even to 40,000 ft. above the earth, where he supposed that the thin air offered little resistance. These statements, which have been widely quoted, are wholly erroneous.

Reliable data on the rate of flight accumulated slowly after 1915. Alexander Wetmore and others secured information on the subject by timing birds flying parallel to roads by means of the speedometer of an automobile. In such diverse forms as herons, hawks, horned larks, ravens and shrikes the usual flight varies from 22 to 28 mi. per hour. The Arkansas kingbird and scissor-tailed flycatcher may fly at only 10 to 17 mi. per hour.

Richard Meinertzhagen gave very definite data on the speed of flight in birds from observations made by theodolites designed to estimate the speed of planes at anti-aircraft stations, by stop watches along measured courses and by observations from travelling planes. From his records it appears that members of the crow family may travel from 31 to 45 mi. per hour, the smaller perching birds, as larks, pipits and buntings from 20 to 37 mi. per hour, starlings from 38 to 49 mi., geese from 42 to 55 mi., ducks 44 to 59 mi., falcons 40 to 48 mi. and sand grouse 43 to 47 mi. per hour. The fastest flying birds known are found in the family of swifts (*Apodidae*). One species (apparently the common swift of Eurasia), observed from an airship in Mesopotamia, circled easily about a plane flying at 68 mi. per hour. From this and other observations it appears that ordinary swifts fly regularly at 70 mi. and may accelerate this to 100 mi. per hour for necessity or pleasure. The speed of falcons in striking at prey is estimated at more than 150 mi. per hour.

The running speed on the ground of Gambel's quail is 11 to 14 mi. per hour, and that of the road runner, a terrestrial cuckoo, 12 to 15 mi. per hour.

FOOD

During their long period of evolution, birds have become adapted to all foods available to their methods of feeding. Geese graze on tender herbage as readily as cattle, rheas and ostriches select a miscellaneous vegetable diet, the plant cutter (*Phytotoma*) eats buds, berries and other vegetable matter, the palm chat of Haiti (*Dulus dominicus*) frequently consumes blossoms, the sage grouse (*Centrocercus urophasianus*) delights in the bitter twigs and leaves of sage (*Artemisia*), ducks are fond of succulent roots, tubers and leaves of aquatic plants and many other birds have similar propensities for plant stems or leaves. Fruits are taken by many birds, while the number of birds that depend upon starchy seeds for the major part of their diet is myriad, and includes a great variety of species. The finches with their strong bills crack off the investing hulls of large seeds and consume only the starchy interior. Small hard seeds, as those of lambs-quarter (*Chenopodium*), are swallowed entire and are ground up by sand and bits of gravel swallowed for the purpose. Grackles (*Quiscalus*) by means of a keeled process on the palate, cut around the shells of acorns until they crack in two and the meat is exposed. Jays hold nuts between the toes and break them open by strong blows of the beak. Some woodpeckers force acorns into crevices in trees, where they are held until they may be broken open. The mallard and wood duck swallow acorns and even entire nuts of the hickory, which have a shell so thick that it requires a strong blow of a hammer to break them, and grind them up in their gizzards. Seeds form a standard autumn and winter food when other sustenance is lacking and are eaten in tremendous quantity. From the stomach and gullet of 1 mallard duck there have been taken 102,400 seeds of the primrose willow (*Jussiaea leptocarpa*).

Birds that feed on insect life abound, and include a large proportion of the smaller species. Vireos, warblers and kinglets search actively for insects among leaves and twigs, picking off their prey at rest or flying out a few inches after some escaping titbit. Flycatchers (*Tyrannidae*) watch from commanding perches and fly out to snap up passing insects on the wing, or occasionally to pick them from the ground. Nuthatches and creepers search over the bark of trees for insects, spiders or eggs hidden in the crevices, and woodpeckers chisel out coleopterous grubs from their hidden tunnels in wood. Usually these are found in decaying trunks, but occasionally some of the stronger woodpeckers will cut in through one inch of hard wood to secure a grub. The flicker (*Colaptes*) feeds much on the ground on ants, which it secures by its long tongue as the insects run about their hills. More than 6,000 ants have been taken from the stomach of one flicker. Swifts, swallows and nightjars feed exclusively on the wing, securing flying insects in their capacious mouths. In the stomach of 1 nighthawk there have been found 50 species of flying insects

comprising several thousand individuals. Cuckoos consume large numbers of hairy caterpillars, from which the stomach becomes so filled with hairs stuck in the lining that its inner surface appears covered with short, stiff fur. Hummingbirds live on the nectar of flowers and tiny flies, Hymenoptera, beetles and spiders that find a home in blossoms or in the bark of trees.

Grebes, divers, herons, mergansers, cormorants and pelicans feed on fish of various kinds, most often on species not especially desirable from a human standpoint. Albatrosses and shearwaters take quantities of squid, and the smaller petrels seem to secure the miscellaneous array of smaller marine creatures known collectively as plankton (*q.v.*). Hawks and owls feed extensively on small mammals and other birds. Some eat frogs, snakes and large insects, as well as crayfish. Larger owls may capture and consume smaller ones, and partly grown brown pelicans, when ravenous with hunger, may seize and swallow a small member of the colony, that has just been fed. The flesh of dead animals, even in the form of putrid carrion, is sought by vultures that eat with impunity where death from poison from bacillary action would be the fate of another creature.

Though most birds seek their food day by day and so live an existence that involves continual search for sustenance, a few species form food stores against a time of scarcity. Most remarkable among these is a group of North American woodpeckers (*Balanosphyra formicivora*), that drill holes in the trunks of trees, in which they fit acorns, and so preserve a part of the acorn harvest for subsequent consumption. The birds work assiduously, since 13,200 acorns have been estimated as the store on 1 large tree trunk, with an average density of 60 to the square foot. That the instinct for storage sometimes goes astray is shown when the carefully drilled holes are filled with pebbles instead of nuts. The red-headed woodpecker (*Melanerpes erythrocephalus*) fills cavities with quantities of acorns or other small nuts, over which it piles bits of bark to conceal them. Many shrikes (*Lanius*), when food is abundant, frequently impale the bodies of grasshoppers, birds, mice or other prey on thorns, to return to them later if needed.

Hawks and owls swallow their prey entire or in large fragments, digest out all nutritive matter and form the bones, fur, scales, feathers or chitin into pellets, which are subsequently regurgitated, leaving the stomach empty to receive another meal. Albatrosses eject pellets composed of the beaks of squids, flycatchers masses of insect chitin, and even hummingbirds may throw up tiny pellets made up of the indigestible portions of their animal food. Birds with strong, muscular gizzards, that feed on seeds, swallow sand or gravel that serve as millstones to triturate into digestible starch meal the seeds they have eaten.

The Brahmans maintain towers where food for birds is placed, and where birds may nest. In Japanese temples shelves are built where swallows may erect their homes. Indians in the eastern United States placed hollow gourds on bare stubs of trees to provide nesting cavities for the purple martin (*Progne subis*), a species of swallow, a practice that was adopted by early colonists from Europe and that is followed today in country districts in the southern states. From these somewhat rude foundations there have developed complicated procedures for the attraction of birds about human homes. The martin gourd has been transformed into ornate martin houses containing many compartments, each of a size to house a pair of birds, and boxes or houses have been designed for many other hole-nesting birds. Though in use in many places, particularly in Germany, at an earlier date, it is since the beginning of the present century that methods for the attraction of birds have received widespread attention. In the United States and Europe single-compartment houses (nesting boxes) are set up for wrens, bluebirds, tits, woodpeckers and similar birds, and where favourably located are occupied without the slightest hesitation. These bird houses are of many types, and so many are used that commercial companies have been formed for their manufacture.

Large pieces of suet tied to the trunks or limbs of trees, where birds may feed without fear of capture from cats, draw woodpeckers, nuthatches and titmice. A shelf built on an outside window ledge will attract many birds where they may be seen to the best advantage. Sunflower and canary seed, wheat, chickfeed, moderately fine-ground corn, nut meats and crumbs of bread are all relished by feathered neighbours. A mixture of suet and nut meats, preferably peanuts, ground medium fine in a food grinder, is especially relished by titmice and jays. Birds come to such feeding stands throughout the year.

ORIGIN AND EVOLUTION

Bizarre as the idea may seem at first, birds are more closely allied to reptiles (*q.v.*) than to any other living group of vertebrates. The bird, while similar to the reptile in much of its structure, in its superior mental capacity, and concomitant adaptations that this has permitted, has far outstripped its lowly cousins, and so has flourished and multiplied while its cold-blooded relatives with decreasing numbers have fallen behind in the race of life. From one viewpoint we may look upon the bird as the attempt of the reptilian groups to retain the dominance of the earth that was theirs during the Mesozoic era, a design that was frustrated by the development of mammals.

The earliest birds known were contemporaneous with dinosaurs (*see* DINOSAURIA), to which, structurally, they seem to have close affinity, particularly to the hollow-boned, agile, birdlike groups. Since these creatures existed at a time when primitive birds were also known, search must be carried farther into the ages for a generalized reptilian group from which both birds and dinosaurs may have sprung. This, apparently, is found in the fossil reptiles known as the Pseudosuchians, of early Triassic times; though according to some the original ancestor of the birdlike creatures should be sought in still older ages in the Permian.

Fossil Birds.—The bones of birds are so poorly preserved in the fossil state that there is record now of only about 800 fossil forms, including some of questionable identity. The earliest fossils known are *Archaeopteryx* (*q.v.*) and *Archaeornis* (*see* ARCHAEOPTERYX) of the Jurassic beds of Bavaria, creatures with toothed jaws, long, bony tails with feathers projecting along the sides and free fingers, that in spite of their reptilian form, were birds, since they were covered with feathers and were able to fly. In the Cretaceous period two types of birds, both possessing teeth, are known from nearly complete skeletons, *Hesperornis* (*q.v.*) and its allies, diverlike species that lived in water and seemed to have had no functional wings, and *Ichthyornis* (*q.v.*) which was aerial and may have had the habits of a gull. These four are the most peculiar fossil birds known at present, since others, while often strange, are allied more or less closely to modern families.

At the beginning of the Tertiary period the types of birds found were suggestive, in form, of existing birds, though in the Eocene some were highly peculiar, and most seem to pertain to extinct families. In the Miocene there occur a number of birds closely similar to those existing today, and in the Pleistocene are found bones of numerous birds still in existence, in addition to many that differed from modern forms.

The progress of the avian group since the coming of the Pleistocene ice seems to have been one of extermination rather than of consistent evolutionary progress, since peculiar types seem to have been exterminated in numbers during the Pleistocene, and there is no indication that others have developed to take their places except for the minor characters that distinguish subspecies or poorly marked species. The story of fossil birds is far from complete, and much work remains to be done on many of those at present discovered, to establish their relationship.

SYSTEMATIC CLASSIFICATION

It is difficult to arrive at an exact figure for the number of kinds of birds now known, but at a conservative estimate it is believed this may reach 28,000 distinct forms.

The primary group or class, Aves, is one of the great divisions of the vertebrates and is equal in rank to the fishes, amphibians, reptiles and mammals. This class is divided into two subclasses, the first, the Archaeornithes, containing the most primitive birds which are very close to reptiles, and the second, the Neornithes, all other known birds. The Neornithes are divided again into

four major divisions or superorders, the Odontognathae, containing forms with teeth, the Palaeognathae, for the ostrichlike birds and their allies, which have a primitive arrangement of the bones of the palate, the Impennes and the Neognathae, including the remaining species with a more specialized modern type of palatal structure. These superorders are divided again into orders, suborders, superfamilies and families. An arrangement embodying modern ideas of classification follows:

Class Aves, Birds
Subclass ARCHAEORNITHES, ancestral birds
Order Archaeopterygiformes, *Archaeopteryx, Archaeornis* (fossil)
Family Archaeopterygidae, *Archaeopteryx* (fossil)
„ Archaeornithidae, *Archaeornis* (fossil)
Subclass NEORNITHES, true birds
Superorder Odontognathae, new world toothed birds
Order Hesperornithiformes, Hesperornithes
Family Hesperornithidae, *Hesperornis, Hargeria* (fossil)
„ Enaliornithidae, *Enaliornis* (fossil)
„ Baptornithidae, *Baptornis* (fossil)
Order Ichthyornithiformes, Ichthyornithes
Family Ichthyornithidae, *Ichthyornis* (fossil)
„ Apatornithidae, *Apatornis* (fossil)
Superorder Palaeognathae, struthious birds and allies
Order Caenagnathiformes, Caenagnathus
Family Caenagnathidae, *Caenagnathus* (fossil)
Order Struthioniformes, ostriches
Family Struthionidae, ostriches (old world)
Order Rheiformes, rheas
Family Rheidae, rheas (South America)
Order Casuariiformes, cassowaries, emus
Family Casuariidae, cassowaries (Australian region)
„ Dromiceidae, emus (Australian region)
„ Dromornithidae, *Dromornis* (fossil)
Order Dinornithiformes, moas
Family Dinornithidae, moas (fossil and extinct, New Zealand)
„ Anomalopterygidae, *Anomalopteryx, Emeus* and allies (fossil and extinct)
Order Aepyornithiformes, elephant birds
Family Aepyornithidae, *Aepyornis* (fossil and extinct, Madagascar)
Order Apterygiformes, kiwis
Family Apterygidae, kiwis (New Zealand)
Order Tinamiformes, tinamous
Family Tinamidae, tinamous (Mexico to South America)
Superorder Impennes, penguins
Order Sphenisciformes, penguins
Family Spheniscidae, penguins (southern hemisphere)
„ Cladornithidae, *Cladornis* (fossil)
Superorder Neognathae, typical birds
Order Gaviiformes, loons
Family Gaviidae, loons (northern hemisphere)
Order Colymbiformes, grebes
Family Colymbidae, grebes (cosmopolitan)
Order Procellariiformes, albatrosses, shearwaters, petrels and allies
Family Diomedeidae, albatrosses (southern hemisphere and North Pacific)
„ Procellariidae, shearwaters, fulmars (cosmopolitan)
„ Hydrobatidae, stormy petrels (cosmopolitan)
„ Pelecanoididae, diving petrels (southern hemisphere)
Order Pelecaniformes, tropic birds, pelicans, frigate birds and allies
Suborder Phaëthontes, tropic birds
Family Phaëthontidae, tropic birds (tropical seas)
Suborder Pelecani, pelicans, boobies, cormorants, snakebirds
Superfamily Pelecanoidea, pelicans and allies
Family Pelecanidae, pelicans (tropics to warm temperate)
„ Cyphornithidae, *Cyphornis, Palaeochenöides* (fossil)
Superfamily Suloidea, boobies, cormorants and allies
Family Pelagornithidae, *Pelagornis* (fossil)
„ Sulidae, boobies, gannets (cosmopolitan)
„ Elopterygidae, *Elopteryx, Eostega, Actiornis* (fossil)
„ Phalacrocoracidae, cormorants (cosmopolitan)
„ Anhingidae, snakebirds (tropics and subtropics)
Suborder Fregatae, frigate birds
Family Fregatidae, frigate birds (tropics and subtropics)
Suborder Odontopteryges, *Odontopteryx, Pseudodontornis* (fossil)
Family Odontopterygidae, *Odontopteryx* (fossil)
„ Pseudodontornithidae, *Pseudodontornis* (fossil)
Order Ciconiiformes, herons, storks and allies
Suborder Ardeae, herons, bitterns
Family Ardeidae, herons, bitterns (cosmopolitan)
„ Cochleariidae, boat-billed herons (tropical America)
Suborder Balaenicipites, whale-headed storks
Family Balaenicipitidae, whale-headed storks (Africa)
Suborder Ciconiae, storks, ibises, spoonbills
Superfamily Scopoidea, hammerheads
Family Scopidae, hammerheads (Africa)
Superfamily Ciconioidea, storks
Family Ciconiidae, storks, jabirus (cosmopolitan)
Superfamily Threskiornithoidea, ibises
Family Threskiornithidae, ibises, spoonbills (cosmopolitan)
Suborder Phoenicopteri, flamingos
Family Agnopteridae, *Agnopterus* (fossil)
„ Scaniornithidae, *Scaniornis, Parascaniornis* (fossil)
„ Phoenicopteridae, flamingos (temperate and tropical regions)
Order Anseriformes, screamers, ducks, geese, swans
Suborder Anhimae, screamers
Family Anhimidae, screamers (South America)
Suborder Anseres, ducks, geese, swans
Family Paranyrocidae, *Paranyroca* (fossil)
„ Anatidae, ducks, geese, swans (cosmopolitan)
Order Falconiformes, vultures, hawks, falcons
Suborder Cathartae, new world vultures
Superfamily Eocathartoidea, Eocathartes
Family Eocathartidae, *Eocathartes* (fossil)
Superfamily Cathartoidea, new world vultures
Family Cathartidae, new world vultures (the Americas)
„ Teratornithidae, *Teratornis, Cathartornis* (fossil)
Suborder Falcones, secretary birds, hawks, falcons
Superfamily Sagittarioidea, secretary birds
Family Sagittariidae, secretary birds (Africa)
Superfamily Falconoidea, hawks, falcons and allies
Family Accipitridae, hawks, old world vultures, harriers (cosmopolitan)
„ Pandionidae, ospreys (cosmopolitan)
„ Falconidae, falcons, caracaras (cosmopolitan)
Order Galliformes, megapodes, curassows, pheasants, hoatzins
Suborder Galli, megapodes, curassows, grouse, pheasants
Superfamily Cracoidea, megapodes, curassows
Family Megapodiidae, megapodes (Australian region)
„ Gallinuloididae, *Gallinuloides* (fossil)
„ Cracidae, curassows, guans, chachalacas (Mexico to South America)
Superfamily Phasianoidea, grouse, pheasants, turkeys
Family Tetraonidae, grouse (cosmopolitan)
„ Phasianidae, quails, pheasants, peacocks (cosmopolitan)
„ Numididae, guinea fowl (Africa)
„ Meleagrididae, turkeys (North America)
Suborder Opisthocomi, hoatzins
Family Opisthocomidae, hoatzins (tropical South America)
Order Gruiformes, cranes, rails and allies
Suborder Mesoenatides, roatelos, monias
Family Mesoenatidae, roatelos, monias (Madagascar)
Suborder Turnices, bustard-quails, hemipodes
Family Turnicidae, bustard-quails (old world)
„ Pedionomidae, collared hemipodes (Australia)
Suborder Grues, cranes, limpkins, trumpeters, rails
Superfamily Gruoidea, cranes, limpkins, trumpeters
Family Geranoididae, *Geranoides* (fossil)
„ Eogruidae, *Eogrus* (fossil)
„ Gruidae, cranes (cosmopolitan, except South America)
„ Aramidae, limpkins (tropical and subtropical America)
„ Psophiidae, trumpeters (South America)
Superfamily Ralloidea, rails
Family Orthocnemidae, *Orthocnemus, Elaphrocnemus* (fossil)
„ Rallidae, rails, coots, gallinules (cosmopolitan)
Suborder Heliornithes, sun grebes
Family Heliornithidae, sun grebes (Africa, southern Asia, tropical America)
Suborder Rhynocheti, kagus
Family Rhynochetidae, kagus (New Caledonia)

Suborder Eurypygae, sun bitterns
Family Eurypygidae, sun bitterns (Central and South America)
Suborder Phororhaci, *Phororhacos* and allies
Family Phororhacidae, *Phororhacos, Pelecyornis* and allies (fossil)
„ Brontornithidae, *Brontornis, Liornis* and allies (fossil)
„ Opisthodactylidae, *Opisthodactylus* (fossil)
Suborder Cariamae, cariamas and allies
Family Bathornithidae, *Bathornis* (fossil)
„ Hermosiornithidae, *Hermosiornis, Procariama* (fossil)
„ Cariamidae, cariamas (South America)
Suborder Otides, bustards
Family Otididae, bustards (old world)
Order Diatrymiformes, *Diatryma, Omorhamphus* and allies
Family Diatrymidae, *Diatryma* (fossil)
„ Gastornithidae, *Gastornis, Remiornis* (fossil)
Order Charadriiformes, shore birds, gulls, auks
Suborder Charadrii, shore birds
Superfamily Jacanoidea, jaçanas
Family Jacanidae, jaçanas (tropics)
Superfamily Charadrioidea, plovers, sandpipers and allies
Family Rostratulidae, painted snipe (cosmopolitan, except North America and Europe)
„ Haematopodidae, oyster catchers (cosmopolitan)
„ Charadriidae, plovers, turnstones, surfbirds (cosmopolitan)
„ Scolopacidae, snipe, woodcock, sandpipers (cosmopolitan)
„ Recurvirostridae, avocets, stilts (cosmopolitan)
„ Presbyornithidae, *Presbyornis* (fossil)
„ Phalaropodidae, phalaropes (cosmopolitan, except Australia)
Superfamily Dromadoidea, crab plovers
Family Dromadidae, crab plovers (India to East Africa)
Superfamily Burhinoidea, thick-knees
Family Burhinidae, thick-knees (cosmopolitan, except North America)
Superfamily Glareoloidea, pratincoles, coursers
Family Glareolidae, pratincoles, coursers (old world)
Superfamily Thinocoroidea, seed snipe
Family Thinocoridae, seed snipe (South America)
Superfamily Chionoidea, sheathbills
Family Chionidae, sheathbills (southern hemisphere)
Suborder Lari, gulls, terns, skimmers
Family Stercorariidae, skuas, jaegers (cosmopolitan)
„ Laridae, gulls, terns (cosmopolitan)
„ Rynchopidae, skimmers (America, southern Asia and Africa)
Suborder Alcae, auks
Family Alcidae, auks, auklets, murres (northern hemisphere)
Order Columbiformes, sand grouse, pigeons, doves
Suborder Pterocletes, sand grouse
Family Pteroclidae, sand grouse (old world)
Suborder Columbae, pigeons and doves
Family Raphidae, dodos, solitaires (Mauritius Réunion, Rodriguez)
„ Columbidae, pigeons, doves (cosmopolitan)
Order Psittaciformes, lories, parrots, macaws
Family Psittacidae, lories, parrots, macaws (cosmopolitan, except northern Eurasia)
Order Cuculiformes, plantain eaters, cuckoos
Suborder Musophagi, plantain eaters
Family Musophagidae, plantain eaters (Africa)
Suborder Cuculi, cuckoos, roadrunners, anis
Family Cuculidae, cuckoos, roadrunners, anis (cosmopolitan)
Order Strigiformes, owls
Family Protostrigidae, *Protostrix* (fossil)
„ Tytonidae, barn owls (cosmopolitan)
„ Strigidae, owls (cosmopolitan)
Order Caprimulgiformes, oilbirds, goatsuckers
Suborder Steatornithes, oilbirds
Family Steatornithidae, oilbirds (northern South America)
Suborder Caprimulgi, frogmouths, goatsuckers
Family Podargidae, frogmouths (India to Australia)
„ Nyctibiidae, potoos (new world tropics)
„ Aegothelidae, owlet-frogmouths (Australian region)
„ Caprimulgidae, goatsuckers (cosmopolitan except eastern Pacific)

Order Apodiformes, swifts, hummingbirds
Suborder Apodi, swifts
Family Aegialornithidae, *Aegialornis* (fossil)
„ Apodidae, swifts (cosmopolitan)
„ Hemiprocnidae, crested swifts (India to New Guinea)
Suborder Trochili, hummingbirds
Family Trochilidae, hummingbirds (new world)
Order Coliiformes, colies
Family Coliidae, colies (Africa)
Order Trogoniformes, trogons
Family Trogonidae, trogons (cosmopolitan except Holarctic region)
Order Coraciiformes, kingfishers, bee eaters, rollers, hornbills
Suborder Alcedines, kingfishers, todies, motmots
Superfamily Alcedinoidea, kingfishers
Family Alcedinidae, kingfishers (cosmopolitan)
Superfamily Todoidea, todies
Family Todidae, todies (Greater Antilles)
Superfamily Momotoidea, motmots
Family Momotidae, motmots (tropical America)
Suborder Meropes, bee eaters
Family Meropidae, bee eaters (old world)
Suborder Coracii, rollers, hoopoes
Family Coraciidae, rollers (old world)
„ Leptosomatidae, cuckoo rollers and ground rollers (Madagascar)
„ Upupidae, hoopoes (Eurasia and Africa)
„ Phoeniculidae, wood hoopoes (Africa)
Suborder Bucerotes, hornbills
Family Bucerotidae, hornbills (Africa and southern Asia)
Order Piciformes, jacamars, barbets, toucans, woodpeckers
Suborder Galbulae, jacamars, barbets, toucans
Superfamily Galbuloidea, jacamars, puffbirds
Family Galbulidae, jacamars (tropical Mexico to South America)
„ Bucconidae, puff-birds (Central and South America)
Superfamily Capitonoidea, barbets, honey guides
Family Capitonidae, barbets (tropics)
„ Indicatoridae, honey guides (Africa and southern Asia)
Superfamily Ramphastoidea, toucans
Family Ramphastidae, toucans (Mexico to South America)
Suborder Pici, woodpeckers
Family Picidae, woodpeckers, piculets (cosmopolitan, except Madagascar and Australia)
Order Passeriformes, perching birds
Suborder Eurylaimi, broadbills
Family Eurylaimidae, broadbills (tropical Africa and Indo-Malaya)
Suborder Tyranni, ovenbirds, tyrant flycatchers and allies
Superfamily Furnarioidea, ovenbirds, wood hewers and allies
Family Dendrocolaptidae, wood hewers (Mexico to South America)
„ Furnariidae, ovenbirds (Mexico to South America)
„ Formicariidae, ant thrushes (Mexico to South America)
„ Conopophagidae, ant pipits (South America)
„ Rhinocryptidae, tapaculos (Central and South America)
Superfamily Tyrannoidea, tyrant flycatchers, pittas and allies
Family Cotingidae, cotingas (new world)
„ Pipridae, manakins (Mexico to South America)
„ Tyrannidae, tyrant flycatchers (new world)
„ Oxyruncidae, sharp-bills (Central and South America)
„ Phytotomidae, plant cutters (South America)
„ Pittidae, pittas (old world tropics)
„ Acanthisittidae, New Zealand wrens (New Zealand)
„ Philepittidae, asities (Madagascar)
Suborder Menurae, lyrebirds
Family Menuridae, lyrebirds (Australia)
„ Atrichornithidae, scrubbirds (Australia)
Suborder Passeres, song birds
Family Alaudidae, larks (cosmopolitan)
„ Palaeospizidae, *Palaeospiza* (fossil)
„ Hirundinidae, swallows (cosmopolitan)
„ Campephagidae, cuckoo shrikes (old world)
„ Dicruridae, drongos (old world tropics)
„ Oriolidae, old world orioles (old world)
„ Corvidae, crows, magpies, jays (cosmopolitan)

Family Paradiseidae, birds of paradise, bowerbirds (Australian region)
" Paradoxornithidae, parrotbills, suthoras (Nepal to China)
" Paridae, titmice (Eurasia, Africa, North America)
" Sittidae, nuthatches (northern hemisphere, Australian region)
" Hyposittidae, coral-billed nuthatches (Madagascar)
" Certhiidae, creepers (Eurasia, North America, Australia)
" Chamaeidae, wren tits (Oregon and California)
" Timaliidae, babbling thrushes (old world)
" Pycnonotidae, bulbuls (old world)
" Cinclidae, dippers (northern hemisphere)
" Troglodytidae, wrens (cosmopolitan, except Africa and Australia)
" Mimidae, thrashers, mockingbirds (new world)
" Turdidae, thrushes (cosmopolitan)
" Zeledoniidae, wren thrushes (Costa Rica and Panamá)
" Sylviidae, old world warblers (cosmopolitan)
" Regulidae, kinglets (northern hemisphere)
" Muscicapidae, old world flycatchers (old world)
" Prunellidae, accentors, hedge sparrows (Europe and northern Asia)
" Motacillidae, wagtails, pipits (cosmopolitan)
" Bombycillidae, waxwings (northern hemisphere)
" Ptilogonatidae, silky flycatchers (tropical America)
" Dulidae, palm chats (Hispaniola)
" Artamidae, wood swallows (Africa, India and Australian region)

BIBLIOGRAPHY.—The literature of ornithology is extensive, with important new works appearing annually. The following list gives a few useful works for consultation on different phases of the subject, in which the student may find other references to a more extensive bibliography. The titles are grouped for convenience under several headings:

General: G. M. Allen, *Birds and Their Attributes* (1925), a readable and accurate general account of birds as a group; Albert R. Brand Bird Song Foundation, *American Bird Songs* (1942), 6 double-disk phonograph records giving songs of 72 birds taken from life; E. M. Nicholson and L. Koch, *Songs of Wild Birds* (London, 1936), phonographic records of songs of British birds; American Ornithologists' Union, *Fifty Years Progress of American Ornithology, 1883–1933* (1933); F. Groebbels, *Der Vogel, Bau, Funktion, Lebenserscheinung, Einpassung* (Berlin, 1932–37), an important general treatise; J. J. Hickey, *A Guide to Bird Watching* (1943), an excellent general treatise for amateur and professional; A. Newton, *A Dictionary of Birds* (London, 1893–96), a vast amount of information arranged in encyclopaedic form; J. A. Thomson, *The Biology of Birds* (London and New York, 1923), a modern account that considers broadly the entire subject.

Migration: F. C. Lincoln, *The Migration of North American Birds* (Dept. of Agriculture, 1935), a concise summary of fact for this continent; A. L. Thomson, *Bird Migration, a Short Account* (London, 1944), a discussion of migration in condensed form; A. Wetmore, *The Migrations of Birds* (1930), a broad review of the entire subject.

Manuals and Life Histories: W. B. Alexander, *Birds of the Ocean* (New York and London, 1928), a convenient manual for travellers by sea; Salim Ali, *The Book of Indian Birds* (Bombay, 1943), with coloured plates as an aid to identification; A. C. Bent, *Life Histories of North American Birds* (1920–46), an excellent general reference work of which 15 vols. have been published, with others in preparation; D. Bannerman, *Birds of Tropical West Africa*, 5 vol. (London, 1930–39), a standard work complete for its area; J. Bond, *Birds of the West Indies* (1936), with descriptions as an aid to identification, and notes on habits; H. R. and J. C. Caldwell, *South China Birds* (Shanghai, 1931), an account of 550 forms recorded from the 5 southern provinces; N. W. Cayley, *What Bird is That? A Guide to the Birds of Australia* (Sydney, 1935), a complete popular guide; F. M. Chapman, *Birds of Eastern North America* (1932), a manual for the study and identification of the birds of this region; F. N. Chasen, *Handlist of Malaysian Birds* (Singapore, 1935), complete list with distribution; J. Delacour and P. Jabouille, *Les oiseaux de l'Indochine française*, 4 vols. (Paris, 1931), gives descriptions for identification, distribution and habits; G. Grosvenor and A. Wetmore, *The Book of Birds*, 2 vols. (1937), descriptive account of North American birds with all species illustrated in colour; M. Hachisuka, *The Birds of the Philippine Islands*, 2 vols. (London, 1931–35), a compilation with many coloured plates; E. Hartert and F. Steinbacher, *Die Vögel der palaarktischen Fauna* (Berlin, 1903–38), an authoritative manual of the birds of Europe and North Asia; F. W. Hutton and J. Drummond, *The Animals of New Zealand* (Christchurch, N.Z., 1905), includes an account of the birds; K. Lambrecht, *Handbuch der Palaeornithologie* (Berlin, 1933), a review of the fossil birds of the world; E. Mayr, *Birds of the Southwest Pacific* (1945), a compact manual for the area between Palau, the Solomon Islands and Samoa; R. T. Peterson, *A Field Guide to the Birds* (1947), a well-illustrated popular manual for the eastern United States and Canada; R. T. Peterson, *Field Guide to Western Birds* (1941), a competent, well-illustrated handbook; A. Roberts, *The Birds of South Africa* (London, 1940), for the region south of the Cunene and Zambesi rivers; W. L. Sclater, *Systema Avium Ethiopicarum* (London, 1924–30), a complete list of the names, with ranges, of the birds of Africa; B. E. Smythies, *Birds of Burma* (Rangoon, 1940), a standard manual with coloured plates as an aid in identification; B. B. Sturgis, *Field Book of Birds of the Panama Canal Zone* (1928), a useful field guide valuable for adjacent areas as well; W. E. Wait, *Birds of Ceylon* (London and Colombo, 1925), for the birds of this interesting island; H. F. Witherby, F. C. R. Jourdain, N. F. Ticehurst and B. W. Tucker, *The Handbook of British Birds*, 5 vols. (London, 1938–41), one of the best works of its kind that has been written; American Ornithologists' Union, *Check-list of North American Birds* (1931), the official list for North America north of Mexico; British Ornithologists' Union, *List of British Birds* (London, 1915), the official list for the British Isles; Royal Australasian Ornithologists' Union, *Official Check-list of the Birds of Australia* (Melbourne, 1926), a list of names with ranges of Australian birds; J. L. Peters, *Check-list of Birds of the World*, 5 vols. (1931–45, *et seq.*), complete for the entire world.

Economic Papers: W. E. Collinge, *The Food of Some British Wild Birds* (York, England, 1924–27), summary of food habits of British birds; J. Henderson, *The Practical Value of Birds* (1927), general account of economic status with extensive bibliography; Biological Survey, U.S. Department of Agriculture, many bulletins by Judd, Beal, McAtee, Fisher, Kalmbach, Wetmore and others, the most comprehensive series of reports on this subject, continued by the fish and wildlife service, U.S. department of the interior.

Periodicals: American Ornithologists' Union, *The Auk*, quarterly journal with articles of general and scientific interest, particularly of the new world; British Ornithologists' Union, *The Ibis* (London), quarterly, articles of general and scientific interest, particularly of the old world; Avicultural Society, *The Avicultural Magazine* (London), monthly, deals with the problems of keeping birds in captivity; National Audubon Society, *Audubon Magazine*, bimonthly, devoted to popular ornithology and bird protection; H. F. & G. Witherby, *British Birds* (London), monthly, popular magazine on current ornithology in the British Isles; Cooper Ornithological Club, *The Condor*, bimonthly, devoted particularly to birds of western North America; Wilson Ornithological Club, *The Wilson Bulletin*, quarterly, covers especially the central regions of North America; Royal Australasian Ornithologists' Union, *The Emu* (Melbourne), devoted to the interests of ornithology in Australia and adjacent islands; Sociedad Ornitológica del Plata, *El Hornero* (Buenos Aires), deals with ornithological studies in Argentina and adjacent countries; Deutsche Ornithologische Gesellschaft, *Journal für Ornithologie* (Berlin) quarterly, for general and technical ornithological articles; Société Ornithologique de France, *L'oiseau et la revue française d'ornithologie* (Paris), quarterly; technical and popular articles on birds. (A. WT.)

ECONOMIC ORNITHOLOGY

Economic ornithology deals with the study of birds in their relation to man and his various activities, such as agriculture, forestry, trade, sport, etc., or in other words, "it is the practical application of the knowledge of birds to the affairs of everyday life." It is a difficult and intricate study and of the greatest importance to mankind.

The scientific study of wild birds from an economic standpoint may be said to date from the publication of a paper by Prevost in 1858, and one by Jenks in 1859. Since then, thanks largely to the workers in the United States department of agriculture (bureau of biological survey), great progress has been made and numerous intensive studies undertaken. As a result it is now almost universally admitted, with very few exceptions, that the wholesale destruction of wild birds as a means of protecting crops, etc., is, economically, an unsound policy. A bird which does a considerable amount of harm at a particular season of the year may more than compensate for it by the nature of the food consumed at another season, and in a like manner a bird which is injurious in one district may be beneficial in another. It must ever be borne in mind that, as a rule, insect-eating birds feed upon those species of insects that are the easiest to obtain, and that the variation in a bird's diet depends to a large extent upon the abundance of the supply and the ease with which it may be obtained. Moreover, where destructive irruptions of insect life occur and wild birds concentrate on one particular species of insect, no especial chance is given for the rise of new fluctuations among the commoner species eaten, for the species which is unusually numerous is so widely distributed among the ordinary food elements. The more numerous insectivorous birds are, both in species and numbers, the fewer and shorter the insect oscillations are likely to be.

The Amount of Food Consumed by Birds.—As a class birds are distinctly beneficial, and experience shows that it is possible to learn with very considerable precision the exact amounts of the different kinds of food that each species requires in a year. This precision is attained by measuring the percentage volumes of the different items of food found in the stomach, crop, etc., during the various months of the year, from a large series of specimens obtained from different localities. This volumetric method, or the expression of the contents in terms of bulk, is much more exact than any numerical count of the different food items, and enables the investigator not only to express himself in exact quantities, but to compare one bird's diet with another; further, it admits of the stating of the definite ratios each element bears to the other. Every bird requires a certain bulk of food per day, not a certain number of insects, seeds, etc., and to estimate correctly the importance of any item in its diet it is necessary to know what proportion the insects, seeds, etc., bear to the standard requirements, and to do so it is necessary to use some method of measurement. Take the case of the skylark. This bird requires about 6 lb. of food per year; in other words 10,000 larks would require about 27 tons of food in a year. Knowing the percentage of food eaten by this species, it is possible to analyze this figure. Of the total bulk of food consumed in a year 35.5% consists of injurious insects, 3.5% of neutral insects, 2.5% of beneficial insects, 9.5% of grain, 1% of leaves, 2% of earthworms, 1% of slugs, 1.5% of miscellaneous animal matter and 43.5% of weed seeds. In other words, the lark benefits the farmer in regard to 36.5% of its food eaten, is neutral in respect of 50.5% and injurious only in respect of 13%. If the debit and credit account is further examined it shows on the former side a loss of 2½ tons of cereals, and on the latter something like 30,000,000 injurious insects and 30,000 slugs. Such a plague of insects left to themselves would have destroyed many more tons of cereals, root crops, etc. Thus, the farmer is undoubtedly the gainer from the activities of this bird by an enormous tonnage of produce.

The Effects of Fluctuations in the Number of Birds.—It is now fully recognized that wherever the insect-feeding birds of a district or of districts are destroyed, either wantonly or through climatic and other causes, there is an accompanying insect oscillation which is not reduced until the balance of bird life is restored. In the case of many insects whose numbers remain relatively constant, the controlling influence is largely, if not entirely, because of the uniformity of the bird life which prevails from year to year. Any factor, therefore, that tends to modify or upset the restraining influences of wild birds in their relationship to injurious insects is distinctly detrimental. In a like manner, where raptorial birds and owls are destroyed, farm vermin, such as rats, voles and mice, rapidly increase in numbers.

Some species of wild birds are injurious because they are too numerous, and as a result there are too many birds feeding upon the same kind of food in a given area, in consequence of which certain species supplement their diet by feeding upon cultivated crops. No better instance of this can be found than the European house sparrow. It has been estimated that in Great Britain alone the losses caused by this species reach the incredible figure of £8,000,000 per annum. Wherever it has been introduced it has increased and spread with startling rapidity, and proved an enemy to the cultivator. Injury to crops invariably proceeds from an excessive number of individuals rather than from the natural habits of the species. Once any species exceeds what may be described as its high-water mark of abundance, its food habits change and it becomes a source of danger to mankind. The failure of a normal source of food supply occasionally leads birds to injure crops which under ordinary conditions they seldom attack. Many fluctuations in number are either only local or temporary, and if not interfered with will adjust themselves.

The contention that insectivorous birds do more harm than good by attacking beneficial insects and parasitized caterpillars does not appear to be well founded. Similarly, those species which feed largely upon the seeds of weeds have been regarded as beneficial, but it is now known that many of these species act as distributors of the seeds. In any economic consideration of such birds it is perhaps best to regard such activities as neutral, but on this point considerable diversity of opinion exists.

The Food of Nestlings.—No consideration of the economic status of wild birds can be complete without a reference to the food of the young birds in the nest. During the first few days of life nestlings consume daily considerably more than their own weight of food and add 20 to 50% to their weight. From sunrise to sunset feeding continues, 200 to 300 visits being paid to the nest by the parent birds. With the exception of doves and pigeons, and aquatic and raptorial species, the food brought to the young consists of caterpillars, soft-bodied insects, spiders, worms and slugs. Moreover, during the whole of the nesting period the parent birds are feeding upon food similar to that fed to the young. "Few people," states H. C. Bryant, "have any realization of the great quantities consumed by birds. For instance, if we consider that there is an average of one meadowlark to every two acres of available land for cultivation (11,000,000 ac.) in the Sacramento and San Joaquin valleys, and that each pair of birds raises an average of four young, each one of which averages one ounce in weight while in the nest, and consumes half of its own weight of food each day, it takes over 343½ tons of insect food each day to feed the young birds in the great valleys alone."

It is difficult to bring home to the mind by an expression of figures the millions of caterpillars, grubs, flies, beetles, etc., that birds consume. Careful investigations have shown that the British song thrush during the breeding season, April to June, consumes on an average 10,080 caterpillars, flies, grubs, etc., per month; assuming that there are 100,000 of these birds in the British Isles, they would account for 3,024,000,000 insects, etc., weighing more than 520 tons. Such a number are capable of destroying in 3 months more than 65,000 tons of produce, and assuming that this was worth £5 per ton, the activities of the thrushes would result in a saving of £325,000. Other species are equally beneficial, so that these figures might be multiplied by 20 or 30, thus showing a saving of produce every spring approaching £10,000,000.

To summarize:—"A careful examination of the circumstances in which birds have done harm leads to the belief that the damage is usually caused by an abnormal abundance of a species within a limited territory. In such cases so great is the demand for food that the natural supply is exhausted and the birds attack some of the products of garden or orchard.

"Economically considered, birds are simply natural forces, and it should be our purpose to ascertain how they may be turned to our greatest advantage. The best economic conditions are probably fulfilled when birds are numerous as species and moderately abundant as individuals. Under such conditions there will be a demand for food of many kinds, without excessive demand for any one kind. The most desirable status would seem to be such a relation of numbers and species between birds and insects that the birds would find plenty of food without preying on useful products, while the insects would be held in such check that they would neither increase to a harmful extent nor be completely exterminated. The proper course to pursue, apparently, is to study the food habits of both birds and insects, to favour the increase of species which seem best adapted to preserve the proper balance, and to reduce the numbers of those that prey too greatly on the products of orchard or farm."—(F. E. L. BEAL.)

COMMERCIAL USES

Game.—Commercially, birds are utilized in various ways. Some are used as food, others are valued for their plumage and others for their guano.

Most game birds are beneficial to agriculture. While accurate statistics are difficult to obtain, there is a larger consumption of such birds today than ever, and most nations have enacted special laws for their preservation. When and where such laws do not exist the danger of extermination is great. In practically all cases the preservation of game birds has, economically, proved of great value.

Eggs.—In some parts of the world the eggs of various species of wild birds are highly esteemed as food, and large quantities are annually gathered, but here again there is the same tendency toward extermination unless the gatherings are limited, or close seasons instituted. In the U.S. and Canada the gathering of the eggs of wild birds is illegal.

Feathers.—The feathers of birds are commercially of considerable value apart altogether from the demand of the millinery trade. There is a large trade carried on for upholstery purposes in which the feathers of gulls, guillemots, puffins, ducks and the domestic fowl are utilized. The soft feathers or down of the eiderduck are preferred to all others because of their superior warmth, lightness and elasticity. Large quantities are imported from Iceland, Greenland and the Faeroe Islands. The great mercantile value of the plumes of the ostrich has led to the establishment of ostrich farms, which yield considerable profits.

What is known as the plumage trade; *i.e.*, the trade in birds' feathers for millinery purposes, has, quite apart from many repulsive aspects, led to more wanton destruction of certain species of birds than all other causes combined. The almost complete extinction of the egrets in the United States between 1880 and 1890 and the appalling destruction of birds of paradise, gulls, terns, grebes, tanagers, orioles, bluebirds and numerous other small birds was a blot on present-day civilization. Restrictive measures have been, or are being, taken in most civilized countries.

Guano.—Prior to the introduction of artificial manures, guano from the various islands of the Pacific ocean was greatly sought after. Although utilized by the Peruvians more than three centuries ago, it was not until the middle of the 19th century that it assumed any importance as an article of commerce. So great was the demand that the better qualities were soon exhausted, and the poorer ones proved unprofitable when compared with the better artificial fertilizers. Small quantities are still collected. Schemes for protection and conservation of the birds and their product have, however, now been introduced.

Legislation.—In the absence, until recent years, of really comprehensive and reliable statistics with reference to the precise economic status of the different species of wild birds, it is not surprising that the various acts and orders relating to the preservation or destruction of wild birds have proved largely abortive. Many of these have been ill-considered and often hastily prepared, others have been largely selfish in nature, while the advocates of uniform protection have indirectly contributed to the wanton destruction of many useful birds. What would be the probable ultimate effect of such legislation was never seriously considered at the time.

In the U.S. and Canada the principles on which legislation has been based are, that all wild birds are the property of the state, hence that without permission no one has a right to destroy them; the state has the right to impose restrictions and birds may be captured, killed, possessed, etc., only under such conditions as the state enacts; in a like manner landowners can kill or capture only as a privilege and according as the law specifically grants.

International co-operation in Europe as regards the protection of wild birds has proved difficult, so many and diverse are the interests of the different countries. Valuable work has, however, been done by the International Ornithological congresses and other organizations. An international committee was founded in London in 1922, and the International Treaty of 1916 between Great Britain and the United States of America for the protection of migratory birds constitutes one of the most important and far-reaching measures in the history of wild-bird protection.

The immediate need of the present is for (1) wide and comprehensive measures that will ensure protection to all noninjurious and beneficial wild birds, and provide adequate repressive measures for those species which have, or do, become too numerous and destructive; (2) the establishment of an ornithological bureau, which would have full control of all matters relating to wild birds, including game birds. Such an organization should be the sole authority for framing new laws or making special local orders, and for granting licences to persons to collect birds or their eggs for scientific or other purposes, or to destroy birds which the bureau considers to be injurious. Such a bureau would of course be in close touch with other similar bodies, so that international action could be taken where desirable.

(*See* EGG; FEATHER.)

BIBLIOGRAPHY.—S. A. Forbes, Papers in *Trans. Ill. State Hort. Soc.* and *Ill. State Laboratory* (1879–1908); W. B. Barrows, A. K. Fisher, H. W. Henshaw, S. D. Judd, F. E. L. Beal, E. R. Kalmbach, W. L. McAtee, A. Wetmore, T. S. Palmer, etc., publications of U.S. Dept. of Agric., *Bulletins of Biol. Bureau, Farmers' Bulletins,* Year Books, etc. (1887 *et seq.*) continued by the Fish and Wildlife Service, U.S. Department of the Interior, since 1940; E. D. Forbush, *Useful Birds and their Protection* (Mass. State Board of Agric., Boston, 3rd ed., 1908); C. M. Weed and N. Dearborn, *Birds in their Relations to Man* (3rd ed., London and Philadelphia, 1924), a popular manual for U.S. and Canada; W. E. Collinge, *The Food of Some British Wild Birds* (2nd ed., York, 1924–27), a comprehensive manual in nine parts, for Great Britain, with full bibl. containing detailed references to U.S. publications mentioned above; J. Henderson, *The Practical Value of Birds* (1927); T. Gilbert Pearson, *Adventures in Bird Protection* (1937). (W. E. C.)

ORNITHOPTER, a flying machine with flapping wings operated either mechanically or manually. The type is of historic interest only, and represents man's attempt to imitate the flight of birds.

(*See* FLIGHT [NATURAL].)

ORODES, the name of two Parthian kings. Orodes I reigned about 57–37 B.C., succeeding his father, Phraates III whom, in conjunction with his brother, Mithradates III, he had murdered. He was in turn murdered by his son and successor, Phraates IV. Orodes II succeeded Phraates V about A.D. 5 and within two years was murdered because of his cruelty. (Joseph. Ant., xviii, 2, 4.)

(*See* PARTHIA; PHRAATES.)

ORONTES, the ancient name of the chief river of Syria, also called Draco, Typhon, Axius, the last name being probably the name whence has sprung the modern name El-ʿĀsī (rebel). Taking its rise on the east side of the Bekaʿ, it flows northward expanding into the lake of Homs, and in the plain of Antioch, it is joined by two tributaries, the Afrīn and Kara-su. It reaches the sea near the small port of Suedia (Seleucia Pieriae). In its 170 mi. course it is mainly unnavigable and of small value for irrigation. Its valley, however, has served as a highway for armies and trade between Egypt and Palestine, and Asia Minor.

OROPUS, an ancient Greek seaport on the Euripus which, falling finally to Athens, remained an Attic town under the Roman empire. The oracle of Amphiarus was there.

(*See* ALTAR.)

OROSIUS, PAULUS (*fl.* 415), historian and theologian, was born in Spain (possibly at Braga in Galicia) toward the close of the 4th century. Having entered the Christian priesthood, he naturally took an interest in the Priscillianist controversy then going on in his native country, and it may have been in connection with this that he went to consult Augustine at Hippo in 413 or 414. After staying for some time in Africa as the disciple of Augustine, he was sent by him in 415 to Palestine with a letter of introduction to Jerome, then at Bethlehem, the result of his arrival being that John, bishop of Jerusalem, was induced to summon at his capital in June 415 a synod at which Orosius communicated the decisions of Carthage and read such of Augustine's writings against Pelagius as had at that time appeared.

Success, however, was scarcely to be hoped for among orientals who did not understand Latin, and whose sense of reverence was unshocked by the question of Pelagius, *et quis est mihi Augustinus?* All that Orosius succeeded in obtaining was John's consent to send letters and deputies to Innocent of Rome; and, after having waited long enough to learn the unfavourable decision of the synod of Diospolis or Lydda in December of the same year, he returned to North Africa, where he is believed to have died.

The earliest work of Orosius, *Consultatio sive commonitorium ad Augustinum de errore Priscillianistarum et Origenistarum,* explains its object by its title; it was written soon after his arrival in Africa, and is usually printed in the works of Augustine along with the reply of the latter, *Contra Priscillianistas et Origenistas liber ad Orosium.*

His next treatise, *Liber apologeticus de arbitrii libertate,* was written during his stay in Palestine, and in connection with the controversy which engaged him there. It is a keen but not always fair criticism of the Pelagian position from that of Augustine. The *Historiae adversum Paganos* was undertaken at the suggestion of Augustine, to whom it is dedicated.

Nearly 200 manuscripts of the *Historiae* have survived. A free abridged translation by King Alfred is still extant. The *editio princeps* of the original appeared at Augsburg (1471), and has been superseded by C. Zangemeister, who has edited the *Hist.* and also the *Lib. apol.* Besides the Old and New Testaments, Orosius appears to have consulted Caesar, Livy, Justin, Tacitus, Suetonius, Florus and a cosmography, attaching also great value to Jerome's translation of the *Chronicles* of Eusebius.

ORPEN, SIR WILLIAM NEWENHAM MONTAGUE (1878–1931), British painter, was born at Stillorgan, County Dublin, on Nov. 27, 1878, and studied at the Dublin Metropolitan School of Art and at the Slade school, London. He was elected A.R.A. in 1910 and R.A. in 1919. He first exhibited at the New English Art club, of which he became a member in 1900, his early work being marked by preoccupation with spacing and silhouette and the use of quiet harmonies of gray and brown, with a note of vivid red or blue. He soon turned to the use of bright colour and the study of light, seen in a series of brilliant portrait interiors such as the "Hon. Percy Wyndham" (1907), "Myself and Venus" (1910, now in Pittsburgh gallery, Pittsburgh, Pa.).

About this time he became well known for his vigorously characterized portraits. During World War I Orpen received an appointment as official artist and in 1918 an exhibition of his war pictures was held in London. Many of these are now in the Imperial War museum. He was created K.B.E. in 1918. He wrote *An Onlooker in France* (1921) and *Stories of Old Ireland and Myself* (1924).

ORPHEUS. The legendary founder of the cult known as Orphism, ὁ Ὀρφικὸς βίος. The derivation of the name is uncertain, possibly from the same root as ὀρφνη, signifying darkness. What original figure, human or divine, lies behind the legend, is unknown; it seems possible, however, that Orpheus is the name or title of Thraco-Phrygian priest-kings, who may have been regarded as incarnating the god Dionysus (*q.v.*) or some similar deity, and were perhaps killed by the worshippers of the god after a period of years (*see* James Frazer, *Golden Bough,* 3rd ed., vi, 99).

Legend.—Orpheus was the son, in most accounts, of the Thracian king Oeagrus (sometimes of Apollo), and a Muse, generally Calliope, sometimes Polyhymnia. He took part in the Argonautic expedition (*see* ARGONAUTS), and there was an Orphic version of that exploit, preserved in a late form in the Orphic *Argonautica.* The best-known episode of his career is that of his marriage. His wife Eurydice was bitten by a serpent (while fleeing from Aristaeus, according to Virgil, *Georg.,* iv, 457; this detail is not found earlier, but the story itself is old and widespread; *see* Rose in *Aberystwyth Studies,* iv, p. 21). Orpheus, inconsolable at her death, went down to Hades to get her back. The infernal deities, softened by his music, allowed her to return, on condition that she should walk behind Orpheus and he should not look back. He broke this condition, and she became a ghost once more (Plato, *Sympos.,* 179 D., seems to allude to a slightly different account). He now refused to have anything more to do with women, and consequently the Thracian women, during a Dionysiac orgy, set upon him and tore him to pieces. His head floated down the Hebrus and finally came ashore on Lesbos, where there was apparently an oracular shrine of Orpheus. The legend may be founded on the practice of the *omophagia* (*see* DIONYSUS).

Orpheus is represented as a musician so marvellous that the wild beasts, and even trees and rivers, came to listen to him. He is also represented as a seer, a founder of mystic rites, particularly Dionysiac, a magician, and later as an astrologer also. Sometimes his adventures tend to be assimilated to the stock incidents in the career of a philosopher, for he is represented as travelling in search of knowledge (as Plato, for example, is said to have visited Egypt).

Several writers speak of him as a sort of missionary of civilization (*e.g.,* Aristophanes, *Frogs,* 1032; Horace, *A.P.,* 391). He is also the reputed author of a number of books, some dating from the time of Peisistratus of Athens (*see* ONOMACRITUS).

The Orphic Doctrines and "Life."—There was no Orphic church but there existed a number of *thiasoi* (conventicles) of initiates into the Orphic mysteries, all having a similar doctrine and rules of life, but lacking any sort of central organization and probably having no common standard of orthodoxy. Orphic initiators (ὀρφεοτελεσταί) were numerous, and are spoken of with the utmost contempt by Plato and others. We hear of Orphism from about the 6th century on, and the doctrine, which seems to have grown out of a combination of the Thraco-Phrygian worship of Dionysus with certain religious speculations characteristic of that age, and probably resulting from the contact of Greece with the east, was in outline as follows. When Zagreus was devoured by the Titans (*see* DIONYSUS) and they were consumed by the thunderbolt, man sprang from their ashes. Hence, man is partly divine (Zagreus), partly desperately wicked (the Titans). It is his chief end to get rid of the latter element, which is accomplished by a life of ritual and moral purity during the soul's incarnation in a series of bodies. When completely purified, it will be freed from the "circle of birth or becoming" (κύκλος τῆς γενέσεως) and be made fully divine. The rules of purity included abstinence from animal food of all kinds, avoidance of polluting actions, such as contact with death or birth, wearing of white garments and other ascetic practices. There were mysteries of some kind, at which we may conjecture that the death of Zagreus was enacted (*see* MYSTERY), also various Dionysiac practices, such as the *omophagia.* In some cases, at least, the Orphic dead were provided with extracts from the sacred writings of their sect, inscribed on gold tablets, containing directions for their conduct in the underworld. Several of these have been recovered (*see* next paragraph). The influence of Orphism on Pythagoreanism was great, so much so that it is often impossible to separate the two, although one was primarily a religion, the other a system of philosophy.

Orphic Literature.—A great number of books existing in antiquity were ascribed to Orpheus, or his son Musaeus. This literature was well known to Pindar and Euripides, and exercised great influence, directly or through Pythagoreanism, on Plato, and probably on Socrates also (*see* A. E. Taylor, *Varia Socratica*). It is now lost save for (1) the gold tablets already mentioned, which clearly contain extracts from a poem dealing with the underworld; (2) a collection of hymns of late date; (3) *Lithica*

(on the virtues of minerals) and the *Argonautica,* also late. There are, however, numerous quotations in writers of various dates, which together make up a large collection of fragments, some early and undoubtedly genuine Orphic, others much later, including palpable forgeries, showing Jewish and other foreign influence. A principal source for these is the controversialists, Christian and pagan, of the 3rd and 4th centuries A.D. Among editions may be mentioned E. Abel, *Orphica* (1885); and O. Kern, *Orphicorum fragmenta* (1922). The former contains the hymns, *Lithica* and *Argonautica.*

The story of Orpheus, as was to be expected of a legend told both by Ovid and Boethius, retained its popularity throughout the middle ages and was transformed into the likeness of a northern fairy tale. In English mediaeval literature it appears in three somewhat different versions: *Sir Orpheo,* a "lay of Brittany" printed from the Harleian manuscript in J. Ritson's *Ancient English Metrical Romances,* vol. ii (1802); *Orpheo and Heurodis* from the Auchinleck manuscript in David Laing's *Select Remains of the Ancient Popular Poetry of Scotland* (new ed. 1885); and *Kyng Orfew* from the Ashmolean manuscript in J. O. Halliwell's *Illustrations of Fairy Mythology* (Shakespeare Soc., 1842). The poems show traces of French influence.

ORPINGTON, a residential urban district (after 1934) of Kent, England, 13¾ mi. S.E. of London, on the S.R. Pop. (est. 1951) 63,344. Area 32.6 sq.mi. The church is Early English.

ORRERY, CHARLES BOYLE, 4th EARL OF (1676–1731), British author, soldier and statesman, the second son of Roger, 2nd earl, born at Chelsea, was educated at Christ Church, Oxford. He translated Plutarch's life of Lysander, and published an edition of the epistles of Phalaris, which engaged him in the famous controversy with Richard Bentley. Orrery was imprisoned for a short time in 1721 on suspicion of being concerned in Layer's Jacobite plot. He died on Aug. 28, 1731. Among the works of Roger, earl of Orrery, will be found a comedy, entitled *As You Find It,* written by Charles Boyle.

ORRERY, ROGER BOYLE, 1ST EARL OF (1621–1679), British soldier, statesman and dramatist, 3rd surviving son of Richard Boyle, 1st earl of Cork, was born on April 25, 1621, created baron of Broghill on Feb. 28, 1627, and educated at Trinity college, Dublin, and, according to Wood, also at Oxford. He travelled in France and Italy, and coming home took part in the expedition against the Scots. He returned to Ireland on the outbreak of the rebellion in 1641 and fought with his brothers at the battle of Liscarrol in Sept. 1642. On the resignation of the marquis of Ormonde, Lord Broghill consented to serve under the parliamentary commissioners till the execution of the king, when he retired from public life.

He was engaged in royalist schemes, however, when Oliver Cromwell visited him, and, explaining that he knew all about his activities, offered him a chance of clearing himself by serving the commonwealth in Ireland. He accepted, and served Cromwell faithfully throughout the Irish campaign.

Orrery was returned to Cromwell's parliaments of 1654 and 1656 as member for the county of Cork, and also in the latter assembly for Edinburgh, for which he elected to sit. He served that year as lord president of the council in Scotland; and when he returned to England, he was included in the inner cabinet of Cromwell's council, and was nominated in 1657 a member of the new house of lords. On Cromwell's death he gave his support to Richard; but since he saw no possibility of maintaining the government, he left for Ireland, where by resuming his command in Munster he secured the island for Charles and anticipated George Monk's overtures by inviting him to land at Cork. He sat for Arundel in the convention and in the parliament of 1661, and at the Restoration was taken into great favour. On Sept. 5, 1660, he was created earl of Orrery. The same year he was appointed a lord justice of Ireland and drew up the act of settlement. He continued to exercise his office as lord-president of Munster till 1668, when he resigned it because of disputes with the duke of Ormonde, the lord-lieutenant.

On Nov. 25 he was impeached by the house of commons for "raising of money by his own authority upon his majesty's subjects," but the proceedings were interrupted by the prorogation of parliament and were not afterward renewed. He died on Oct. 26, 1679.

In addition to Lord Orrery's achievements as a statesman and administrator, he gained some reputation as a writer and a dramatist. He was the author of *An Answer to a Scandalous Letter . . . A Full Discovery of the Treachery of the Irish Rebels* (1662), printed with the letter itself in his *State Letters* (1742), another answer to the same letter entitled *Irish Colours Displayed . . .* being also ascribed to him; *Parthenissa, a novel* (1654); *English Adventures by a Person of Honour* (1676), whence Thomas Otway drew his tragedy of the *Orphan; Treatise of the Art of War* (1677), a work of considerable historical value; poems, of little interest, including verses *On His Majesty's Happy Restoration* (unprinted), *On the Death of Abraham Cowley* (1677), *The Dream* (unprinted), *Poems on Most of the Festivals of the Church* (1681); plays in verse, of some literary but no dramatic merit, of which *Henry V* (1664), *Mustapha* (1665), *Tryphon* (acted 1668), *The Black Prince* (1669), *Herod the Great* (published 1694) and *Altemira* (1702) were tragedies, and *Guzman* (1669) and *Mr. Anthony* comedies. A collected edition was published in 1737, to which was added the comedy *As You Find It. The General* is also attributed to him.

ORRISROOT (apparently a corruption of iris root), the rhizomes or underground stems of three species of *Iris, I. germanica, I. florentina* and *I. pallida,* closely allied plants growing in subtropical and temperate latitudes, but principally identified with north Italy.

The three plants are indiscriminately cultivated in the neighbourhood of Florence as an agricultural product under the name of ghiaggiuolo.

In August the rhizomes are dug up and freed of the rootlets and brown outer bark; they are then dried and packed in casks for sale. In drying they acquire a delicate but distinct odour of violets. They are principally powdered for use in dentifrices and other scented dry preparations.

ORRVILLE, a city of Wayne county, northeastern Ohio, U.S. It is about 44 mi. S. of Cleveland and is served by the Pennsylvania and the New York, Chicago and St. Louis railways.

The population was 5,153 in 1950 and was 4,484 in 1940 by the federal census.

Products manufactured include castings, hardware, truck bodies, lumber and boiler-room equipment; there is also a meat-packing plant. Agricultural produce of the area includes dairy products and grain.

The city owns and operates a waterworks, a sewage treatment plant and an electric generator. The public library contains more than 10,000 volumes. A semiweekly newspaper, the *Courier-Crescent,* which was established in 1868, is published there.

ORSHA (Polish, Orsza), a town of the White Russian S.S.R., in 54° 34′ N., 30° 20′ E., on the Dnieper river, and at a junction

on the Moscow-Warsaw railway. Pop. (1933) 32,200. It is an entrepôt for grain and timber and has iron works and a brewery. It is mentioned in the annals in 1067 as Rsha and was captured by the Lithuanians in the 13th century.

A Polish Jesuit college was founded there in 1604. During the 16th and 17th centuries it was several times besieged by the Russians, and finally annexed in 1772.

ORSINI, the name of a Roman princely family of great antiquity. According to tradition the popes Paul I (757) and Eugenius II (824) were of the Orsini family, but the probable founder of the house was a certain Ursus (the Bear), about whom little is known, and the first authentic Orsini pope was Giacinto Orsini, son of Petrus Bobo, who assumed the name of Celestin III (1191).

The latter endowed his nephews with church lands and founded the fortunes of the family, which alone of the Guelph houses was able to confront the Ghibelline Colonna. "Orsini for the church" was their war cry in opposition to "Colonna for the people." In the 13th century the "Sons of the Bear" were already powerful and rich, and under Innocent III they waged incessant war against other families, including that of the pope himself (Conti).

In 1241 Matteo Orsini was elected senator of Rome, and sided with Pope Gregory IX against the Colonna and the Emperor Frederick II, saving Rome for the Guelphic cause. In 1266 the family acquired Marino, and in 1277 Giovanni Orsini was elected pope as Nicholas III.

When Boniface VIII proclaimed a crusade against the Colonna in 1297, the Orsini played a conspicuous part in the expedition and captured Nepi, which the pope granted them as a fief. On the death of Benedict XI (1304) fierce civil warfare broke out in Rome and the Campagna for the election of his successor, and Cardinal Napoleone Orsini appears as the leader of the French faction at the conclave. The Campagna was laid waste by the feuds of the Orsini, the Colonna and the Caetani. At this time the Orsini held the castle of S. Angelo, and palaces on the Monte Giordano, which formed a fortified and walled quarter.

In 1332, during the absence of the popes at Avignon, the feuds between Orsini and Colonna, in which even Giovanni Orsini, although cardinal legate, took part, reduced Rome to a state of complete anarchy. The Orsini were again at war with the Colonna at the time of Rienzi. In 1435 Francesco Orsini was appointed prefect of Rome, and created duke of Gravina by Pope Eugenius IV. In 1484 war between the Orsini and the Colonna broke out once more, the former supporting the pope (Sixtus IV). Virginio Orsini led his faction against the rival house's strongholds, which were stormed, the Colonna being defeated.

The Orsini fortunes waxed and waned many times, and their property was often confiscated, but they always remained a powerful family and gave many soldiers, statesmen and prelates to the church. The title of prince of Solofra was conferred on them in 1620, and that of prince of the Holy Roman empire in 1629. In 1724 Vincenzo Maria Orsini was elected pope (Benedict XIII) and gave his family the title of Roman princes.

ORSINI, FELICE (1819–1858), Italian revolutionist, was born at Meldola in Romagna He joined the Giovane Italia, a society founded by Giuseppe Mazzini. Implicated together with his father in revolutionary plots, he was arrested in 1844 and condemned to imprisonment for life. The new pope, Pius IX, released him, and he led a company of young Romagnols in the first war of Italian independence (1848). He was elected member of the Roman constituent assembly in 1849, and after the fall of the republic he conspired against the papal autocracy once more in the interest of the Mazzinian party.

Mazzini sent him on a secret mission to Hungary, but he was arrested in 1854 and imprisoned at Mantua, escaping a few months later. His account of his prison experiences, *Austrian Dungeons in Italy* (1857), led to a rupture between him and Mazzini.

He then formed a plot to assassinate Napoleon III, whom he regarded as the principal obstacle to Italian independence. On the evening of Jan. 14, 1858, while the emperor and empress were on their way to the theatre, Orsini and his accomplices threw three bombs at the imperial carriage. The intended victims were unhurt, but several other persons were killed or wounded. Orsini was arrested; on Feb. 11 he wrote a letter to Napoleon, exhorting him to take up the cause of Italian freedom. He addressed another letter to the youth of Italy, stigmatizing political assassination. He was executed on March 13, 1858.

Of his accomplices, Joseph Pieri also was executed, Rudio was condemned to death but obtained a commutation of sentence and Gomez was condemned to hard labour for life. Orsini's attempt terrified Napoleon, who may have been so induced to take up Italy's cause.

O.* (Milan, 1861); Enrico Montazio, *I contemporanei Italiani-Felice Orsini* (Turin, 1862); *La vérité sur Orsini, par un ancien proscrit* (1879); Angelo Arboit, *Tofin e la fuga di Felice Orsini* (Cagliari, 1893).

ORTA, LAKE OF, in north Italy, west of Lago Maggiore. Its southern end is about 22 mi. by rail N.W. of Novara on the main Turin-Milan line, while its north end is about 4 mi. by rail S. of the Gravellona-Toce railway station. It has an area of about $6\frac{1}{4}$ sq.mi., it is about 8 mi. in length, its greatest depth is 469 ft. and the surface is 951 ft. above sea level, while its width varies from $\frac{1}{2}$ to $1\frac{1}{4}$ mi. The island of San Giulio (just west of the village of Orta) has a picturesque church. The chief place is Orta, on a peninsula projecting from the east shore of the lake, while Omegna is at its northern extremity. The lake is the remnant of a larger sheet of water by which the waters of the Toce flowed south toward Novara. As the glaciers retreated, the waters flowing from them sank and were gradually diverted into Lago Maggiore.

This explains why no considerable stream feeds the Lake of Orta, while at its north end the Nigoglia torrent flows out of it, ultimately joining Lago Maggiore.

ORTELIUS (Wortels), **ABRAHAM** (1527–1598), next to Mercator the greatest geographer of his age, was born at Antwerp on April 14, 1527, and died in the same city on July 4, 1598. He was of German origin, his family coming from Augsburg. He travelled extensively in western Europe. Beginning as a map engraver, he became a merchant, and most of his journeys before 1560 were for commercial purposes. In 1560, however, when travelling with Gerhard Kremer (*see* Mercator, Gerardus), he became interested in scientific geography and began to prepare that atlas or *Theatre of the World* by which he became famous. In 1564 he completed a *mappemonde,* which afterward appeared in the *Theatrum.* In 1570 (May 20) was issued, by Gilles Coppens de Diest at Antwerp, Ortelius' *Theatrum Orbis Terrarum,* the "first modern atlas" (of 53 maps). Many editions, Flemish, Latin and German, appeared in his lifetime. Most of the maps were admittedly reproductions (a list of 87 authors is given by Ortelius himself), and many discrepancies of delineation or nomenclature occur; but, taken as a whole, this atlas with its accompanying text was a monument of rare erudition and industry. In 1573 Ortelius published 17 supplementary maps under the title of *Additamentum Theatri Orbis Terrarum.*

In 1575 Ortelius was appointed geographer to the king of Spain, Philip II, on the recommendation of Arius Montanus, who vouched for his orthodoxy (his family, as early as 1535, had fallen under suspicion of Protestantism). Other important works are: *Synonymia geographica* (1578); *Nomenclator Ptolemaicus* (1584); his *Parergon* (a series of maps illustrating ancient history, sacred and secular), and his *Itinerarium per nonnullas Galliae Belgicae partes,* a record of a journey in Belgium and the Rhineland made in 1575; an edition of Caesar (*C. I. Caesaris omnia quae extant,* Leyden, Raphelingen, 1593) and the *Aurei saeculi imago, sive Germanorum veterum vita* (Philippe Galle, Antwerp, 1596). He also aided Welser in his edition of the Peutinger Table in 1598. His death and burial (in St. Michael's Abbey church) in 1598 were marked by public mourning.

See Emmanuel van Meteren, *Historia Belgica* (Amsterdam, 1670); General Wauwermans, *Histoire de l'école cartographique belge et anversoise* (Antwerp, 1895), and article "Ortelius" in *Biographie nationale* (Belgian), vol. xvi (Brussels, 1901); J. H. Hessels, *Abrahami Ortelii epistulae* (Cambridge, 1887); Max Rooses, *Ortelius et Plantin* (1880); Génard, "Généalogie d'Ortelius," in the *Bulletin de la Soc. roy. de Géog. d'Anvers* (1880 and 1881).

ORTHEZ, a town of S.W. France, department of Basses-Pyrénées, 25 mi. N.W. of Pau on the Southern railway. Pop. (1946) 4,872.

At the end of the 12th century Orthez passed from the viscounts of Dax to the viscounts of Béarn, who resided there in the 13th century. Jeanne d'Albret founded a Calvinist university in the town and Theodore Beza taught there for some time. An envoy sent in 1569 by Charles IX to revive the Catholic faith was besieged in Orthez, which was taken by the Protestant captain, Gabriel, count of Montgomery. In 1684 Nicholas Foucault, intendant under Louis XIV, was more successful, as the inhabitants, ostensibly at least, renounced Protestantism, which however is still strong there. It stands on the right bank of the Gave de Pau there crossed by a 14th-century bridge with four arches and surmounted by a central tower. The Tour de Moncade, a pentagonal tower of the 13th century, was once the keep of a castle of the viscounts of Béarn and is now used as a meteorological observatory. The work of spinning and weaving cotton, especially of the fabric called *toile de Béarn,* the manufacture of paper and of leather and the preparation of hams known as *jambons de Bayonne* and of other delicacies are carried on.

ORTHOCLASE, an important rock-forming mineral belonging to the felspar group (*see* FELSPAR).

ORTHODONTIA, a special department of dentistry concerned with the prevention and correction of irregular and of malposed teeth. Orthodontic treatment is usually effected by means of the spring force of delicate wires attached to the teeth. The earliest attempt in the literature at systematic treatment of orthodontia was by Fauchard in 1728. In 1836 Kneisel published a special work on the subject. Between these two it was variously treated by several writers in the field of mechanical dentistry (Bunon 1743; Bourdet 1757; Fox 1803; Delabarre 1819). At the beginning of the 20th century in America orthodontia emerged from the general field of mechanical dentistry as a recognized specialty. Its advent was heralded by the appearance of many "systems of regulating." These systems were marketable combinations of mechanical appliances designed to effect various movements of the teeth, and were identified by the names of their inventors (Angle, Case, Jackson, *et al*). While this period of the exploitation of apparatus undoubtedly was a great stimulus to the development of technique, the literature which it evoked took the form of personal opinion rather than the presentation of scientific evidence. Expert technicians soon demonstrated the limitations of the mechanical conception of the subject whereupon interest centred in its biological aspect. Since then the results of treatment have been more satisfactory. Great advances have been made in America where specialization is more common while the conservative influence of the dental profession in Great Britain and European countries has acted as a stabilizing force in its growth. The condition of irregular and malposed teeth (*i.e.,* malocclusion) may be caused by bad diet in both its chemical and physical aspects (Howe, McCollum, Mellanby). Habits of infancy and childhood as thumb-sucking, tongue-biting and mouth-breathing, and mutilations from trauma and disease are also important causes. In fact any abnormal function in or about the mouth when persisted in may result in irregular and malposed teeth. (A. L. J.)

ORTHODOX CATHOLIC CHURCH: *see* ORTHODOX EASTERN CHURCH.

ORTHODOX EASTERN CHURCH (frequently spoken of as the Greek Church and described officially as The Holy Orthodox Catholic Apostolic Eastern Church), the historical representative of the churches of the ancient east. It consists of (1) those churches which accepted all the decrees of the first seven general councils and have remained in full communion with one another, (2) such churches as derived their origin from these by missionary activity, or by abscission without loss of communion.

Origins of the Greek or Eastern Church.—Christianity arose in the east, and Greek was the language of the Scriptures and early services of the church, but when Latin Christianity established itself in Europe and Africa, and when the old Roman empire fell in two and the eastern half became separate in government, interests and ideas from the western, the term Greek or Eastern Church acquired gradually a fixed meaning. It denoted the church which included the patriarchates of Constantinople, Alexandria, Antioch and Jerusalem and their dependencies. The ecclesiastical division of the early church, at least within the empire, was based upon the civil. Constantine introduced a new partition of the empire into dioceses, and the church adopted a similar division. The bishop of the chief city in each diocese naturally rose to a pre-eminence, and was commonly called exarch —a title borrowed from the civil jurisdiction. In process of time the common title patriarch was restricted to the most eminent of these exarchs, and councils decided who were worthy of the dignity. The council of Nicaea recognized three patriarchs—the bishops of Rome, Alexandria and Antioch. To these were afterward added the bishops of Constantinople and Jerusalem.

When the empire was divided, there was one patriarch in the west, the bishop of Rome, while in the east there were at first two, then four. At present there are seven. This geographical fact has had a great deal to do in determining the character of the Eastern Church. It is not a despotic monarchy governed from one centre and by a monarch in whom plenitude of power resides. It is an oligarchy of the great body of bishops, ranging through the various grades of metropolitan, archbishop, exarch and patriarch. Each head of an autocephalous church (whether patriarch, exarch or archbishop) is supreme and not amenable to any of his peers but is within the jurisdiction of an ecumenical council. The schismatic churches of the east have always reproduced the ecclesiastical policy of the church from which they seceded.

The Byzantine Church, like the Roman, soon spread far beyond the imperial dioceses which at first fixed its boundaries, but it was far less successful than the Roman in preserving its conquests for Christianity. This was due in the main to the differing quality of the forces by which the area covered by the two churches was respectively invaded. Byzantine Christianity became the religion of the majority of the Slavs as Latin Christianity became that of the Germans; but the Orthodox Church never conquered its conquerors. The great dogmatic work of the Eastern Church was the definition of that portion of the creed of Christendom which concerns theology proper—the doctrines of the essential nature of the Godhead and the doctrine of the Godhead in relation with manhood in the incarnation.

All the churches of the east, schismatic as well as Orthodox, accept unreservedly the decrees of the first two councils. The schismatic churches protest against the additions made to the creeds of Nicaea and Constantinople by succeeding councils. The Niceao-Constantinopolitan creed declared that Christ was consubstantial (ὁμοούσιος) with the Father, and that He had become man (ἐνανθρωπήσας). Disputes arose when theologians tried to explain the latter phrase. These differences took two separate and extreme types, the one of which separated the two natures so as to assert a union by means of the harmony of the divine and human wills, while the other insisted upon an absorption of the human nature in the divine. The former was the creed of Nestorianism, the latter of Monophysitism. The Nestorians accept the decisions of the first two councils and reject the decrees of all the rest as unwarranted alterations of the creed of Nicaea. The Monophysites accept the first three councils but reject the decree of Chalcedon and all that come after it. They gave rise to numerous sects and to at least three separate national churches,—the Jacobites of Syria, the Copts of Egypt and the Abyssinian Church, which are treated under separate headings. (*See* also NICAEA, COUNCIL OF; CHALCEDON, COUNCIL OF; NESTORIUS; NESTORIANS; MONOPHYSITES.)

CONFLICT WITH ROME

The relation of the Byzantine Church to the Roman may be

described as one of growing estrangement from the 5th to the 11th century and a series of abortive attempts at reconciliation since the latter date. The estrangement and final rupture may be traced to political and cultural causes as well as the increasing claims of the Roman bishops and to western innovations in practice and in the doctrine of the Holy Spirit, accompanied by an alteration of creed. In the early church three bishops stood forth prominently, principally from the political eminence of the cities in which they ruled—the bishops of Rome, Alexandria and Antioch. The transfer of the seat of empire from Rome to Constantinople gave the bishops of Rome a possible rival in the patriarch of Constantinople, but the absence of an overawing court and of meddling statesmen did more than recoup the loss to the head of the Roman Church. The theological calmness of the west, amid the violent theological disputes which troubled the eastern patriarchates, and the statesmanlike wisdom of Rome's greater bishops, combined to give a unique position to the pope, which councils in vain strove to shake and which in time of difficulty the eastern patriarchs were fain to acknowledge and make use of, however they might protest against it and the conclusions deduced from it.

But this pre-eminence, or rather the Roman idea of what was involved in it, was never acknowledged in the east; to press it upon the eastern patriarchs was to prepare the way for separation, to insist upon it in times of irritation was to cause a schism. The theological genius of the east was different from that of the west. The eastern theology had its roots in Greek philosophy, while a great deal of western theology was based on Roman law. This gave rise to misunderstandings, and at last led to two widely separate ways of regarding and defining one important doctrine—the procession of the Holy Spirit from the Father or from the Father and the Son. Political jealousies and interests intensified the disputes; and at last, after many premonitory symptoms, the final break came in 1054, when Pope Leo IX smote Michael Cerularius and his adherents in the Eastern Church with an excommunication. There had been mutual excommunications before, but they had not resulted in permanent schisms. Now, however, the separation was final, and the ostensible cause of its finality was the introduction by the Latins of two words *Filioque* into the creed. (After the words "and in the Holy Ghost" of the Apostles' Creed the Constantinopolitan creed added "who proceedeth from the Father." The Roman Church, without the sanction of an ecumenical council and without consulting the easterns, added "and the Son." The addition was first made at Toledo [589] in opposition to Arianism. The easterns also resented the Roman enforcement of clerical celibacy, the limitation of the right of confirmation to the bishop and the use of unleavened bread in the Eucharist.) It is this addition which was and which still remains the permanent cause of separation. Other causes were added later.

Doctrines and Creeds.—The Eastern Church has no creeds in the modern western use of the word, no normative summaries of what must be believed. It has preserved the older idea that a creed is an adoring confession of the church engaged in worship; and, when occasion called for more, the belief of the church was expressed more by way of public testimony than in symbolical books. Still the doctrines of the church can be gathered from these confessions of faith. The eastern creeds may thus be roughly placed in two classes—the ecumenical creeds of the early undivided church, and later testimonies defining the position of the Orthodox Church of the east with regard to the belief of the Roman Catholic and of Protestant Churches. These testimonies were called forth mainly by the protest of Orthodox theologians against Jesuitism on the one hand and against the reforming tendencies of the patriarch Cyrillos Lucaris (*q.v.*) on the other. The Orthodox Church adopts the doctrinal decisions of the seven ecumenical councils, together with the canons of the Concilium Quinisextum or second Trullan council (692); and they further hold that all these definitions and canons are simply explanations and enforcements of the Nicaeo-Constantinopolitan creed and the decrees of the first council of Nicaea. The first four councils settled the orthodox faith on the doctrines of the Trinity and of the two natures of the one person of Jesus Christ; the fifth supplemented the decisions of the first four. The sixth declared against Monothelitism; the seventh sanctioned the worship (*δουλεία*, not *ἀληθινὴλατρεία*) of images; the council held in the Trullus (a saloon in the palace at Constantinople) supplemented by canons of discipline the doctrinal decrees of the fifth and sixth councils.

The most important later doctrinal testimonies of the Eastern Churches are: (1) the Orthodox profession of faith of Peter Mogila, confirmed by the eastern patriarchs and by the synod of Jerusalem (1643), and (2) the decree of the synod of Jerusalem or the confession of Dositheus (1672). Besides these, the answer of the eastern patriarchs to Pius IX (1849) may likewise be included. But none of these is authoritative in the western credal sense.

The Church of Christ is the fellowship of ALL THOSE WHO ACCEPT AND PROFESS ALL THE ARTICLES TRANSMITTED BY THE APOSTLES AND APPROVED BY GENERAL SYNODS. *Without this visible church there is no salvation.*[1] It is under the abiding influence of the Holy Ghost, and *therefore cannot err in matters of faith.* Specially appointed persons are necessary in the service of the church, *and they form a threefold order, distinct jure divino from other Christians, of bishops, priests and deacons.* THE PATRIARCHS HAVE THE HIGHEST RANK AMONG THE BISHOPS, AND THE BISHOPS *united in a general council represent the church and decide,* under the guidance of the Holy Ghost, all matters of faith and ecclesiastical life. But it is only as the decisions of the councils have been accepted by the whole body of believers, clergy and laymen alike, that they become authoritative as living tradition. All ministers of Christ must be regularly called and appointed to their office and are consecrated *by the sacrament of orders. Bishops must be unmarried,* and PRIESTS AND DEACONS MUST NOT CONTRACT A SECOND MARRIAGE. To all priests in common belongs, besides the preaching of the word, the administration of the SIX SACRAMENTS—BAPTISM, CONFIRMATION, PENANCE, EUCHARIST, MATRIMONY, UNCTION OF THE SICK. The *bishops* alone can administer the seventh, the *sacrament* of orders.

Ecclesiastical ceremonies are part of the divine liturgy; most of them have apostolic origin; and those connected with the sacrament must not be omitted by priests under pain of mortal sin.

Liturgy and Worship.—The ancient liturgies of the Eastern Church were numerous but a strong desire for uniformity led to the almost exclusive use of the liturgy of Jerusalem or of St. James. It is used in two forms, a shorter revised by Chrysostom, and a longer called the liturgy of St. Basil. This liturgy and the service generally are either in Old Greek or in Church Slavonic, and frequent disputes have arisen in particular districts about the language to be employed. Both sacred languages differ from the language of the people, but it cannot be said that in the Eastern Church worship is conducted in an unknown tongue—"the actual difference," says J. M. Neale, "may be about that between Chaucer's English and our own." There are 11 chief service books and no such compendium as the Roman breviary. Fasting is frequent and severe. Besides Wednesdays and Fridays, there are four fasting seasons, Lent, Pentecost to SS. Peter and Paul, Aug. 1–15 preceding the Feast of the Sleep of the Theotokos and the six weeks before Christmas. Indulgences are not recognized; an intermediate and purificatory state of the dead is held but not systematized into a doctrine of purgatory. The Virgin receives homage, but the dogma of her Immaculate Conception is not admitted. While ikons are found in the churches, there is no "graven image" apart from the crucifix.

Monasticism is, as it has always been, an important feature in the Eastern Church. An Orthodox monastery is perhaps the most perfect extant relic of the 4th century. The simple idea that possesses the monks is that of fleeing the world; they have no distinctions of orders, and though they follow the rule of St. Basil object to being called Basilians. A few monasteries (Mt. Sinai and some on Lebanon) follow the rule of St. Anthony. K. Lake in *Early Days of Monasticism on Mount Athos* (1909) traces the development through three well-defined stages in the

[1] Small capitals denote differences from Roman Catholic, italics differences from Protestant, doctrine.

9th and 10th centuries—(1) the hermit period, (2) the loose organization of hermits in lauras, (3) the stricter rule of the monastery, with definite buildings and fixed rules under an ἡγούμενος or abbot. (*See* ABBEY; MONASTICISM and related articles.)

The Branches of the Church.—In the early years of the 20th century the Orthodox Eastern Church consisted of 13 mutually independent churches, using their own language in divine service (or some ancient form of it, as in the Greek-speaking churches, Russia and other Slavic churches) and varying not a little in points of detail, but standing in full communion with one another and united as equals in what has been described as one great ecclesiastical federation. However, in using such language it must be remembered that we are not dealing with bodies which were originally separated from one another and have now entered into fellowship, but with bodies which have grown naturally from a single origin and have not become estranged. The most ancient of these divisions depended on the jurisdiction of the four patriarchates. (1) The ancient patriarchate of Constantinople included the imperial dioceses of Pontus, Asia, Thrace and eastern Illyricum; *i.e.*, speaking roughly, the greater part of Asia Minor, European Turkey and Greece, with a small portion of Austria-Hungary. The ecumenical patriarch, as he has been called since early in the 6th century, was the most exalted ecclesiastic of the eastern churches, and his influence reached far outside the lands of the patriarchate. His jurisdiction extended over all the dominions of the sultan. There were 82 metropolitans under him and the "monastic republic" of Mount Athos. He had great privileges and responsibilities as the recognized head of the Greek community in Turkey and enjoyed also many personal honours which had survived from the days of the eastern emperors. (2) The patriarchate of Alexandria, consisting of Egypt and its dependencies, was at one time the most powerful, as it was the most centralized, of all; but the secession of the greater part of the church to Monophysitism, and the Mohammedan conquest of Egypt, have left the patriarch but the shadow of his former greatness. (3) The patriarchate of Antioch has undergone most changes in extent of jurisdiction, arising from the transfer of sees to Constantinople and Jerusalem, from the progress of the schismatic churches of the east and from the conquests of the Mohammedans. The patriarch retains little of his old importance. His jurisdiction includes Cilicia, Syria (except Palestine) and Mesopotamia. After 1899 the native Syrian element secured supremacy. (4) The Patriarchate of Jerusalem was constituted at the council of Chalcedon in 451, with jurisdiction over Palestine. The inroads of the Saracens reduced its importance. At present, the numerically insignificant Greek monastic brotherhood is trying to retain control over the Arabic majority. (X.)

Russian Church.—Although the ancient patriarchates (particularly the ecumenical) still enjoy the highest rank, other Orthodox Churches have far outstripped them in numbers, importance and influence. The Russian Church, for instance, has been, ever since the downfall of the Byzantine empire, the dominant member of Orthodox Christendom. Russia's conversion to Christianity took place in the reign of the grand prince Vladimir (988). It became a metropolitanate of the patriarchate of Constantinople. This situation persisted until 1448, when the Russian Church chose a native for the metropolitan see. By this act it repudiated its dependence upon Constantinople, on the ground that the latter had betrayed orthodoxy by the terms of union with Rome at the council of Florence (1439). It was then the only large Orthodox Church not subject to the Turks. In 1589 it obtained the patriarchal rank; but what is more important, it had long before regarded itself as possessing hegemony of orthodoxy.

In 1666, as the result of the reforming projects of Patriarch Nikon, the Russian Church suffered a schism. The schismatics (*Raskolniki*) repudiated the state church as corrupted by the reforms.

Even greater calamity overtook the church in the reign of Tsar Peter. Upon the death of Patriarch Adrian (1700), Peter refused to allow the election of another patriarch. In 1721 he abolished the patriarchate altogether and radically reorganized the church by creating as the highest administrative organ the Holy Governing synod. By this measure he subordinated the church to the state.

The 19th century may be regarded as the flowering of Russian culture; the astounding creativity of the Russian writers and thinkers won for them a dominant place. Two schools of thought developed: the Westernists, who became revolutionaries in politics, materialists in science and philosophy and atheists in religion. The other school, the Slavophils, developed the native cultural elements. A group loosely associated with them created out of the native religious elements the modern Orthodox world view which seems likely to revivify entire eastern orthodoxy. Among the chief figures of this movement—all laymen—were A. S. Khomyakov, F. M. Dostoievski, V. S. Soloviev and N. A Berdyaev.

Serbian Church.—The other Slavic Orthodox Churches comprise the Serbian and the Bulgarian. The former goes back for its autonomy to 1219, when an independent metropolitanate was organized by St. Sava. It gained the patriarchal rank in 1346 during the reign of the mighty tsar Stephen Dushan. But when Serbia fell prey to the Turks at the fateful battle of Kosovo (1389), a chaotic condition set in. For about five centuries the Serbs bore the heavy Turkish yoke. In 1766 the patriarchate of Pech was abolished and the Serbian Church subjected to the ecumenical patriarch. The fateful rule of the Greek Phanariots left its legacy of hatred to this day. Nevertheless, the church succeeded in preserving, during those dark times, whatever national spirit was left among the degraded Serbian peasants.

But a good-sized group of Serbs escaped the domination of the Turks and of the ecumenical patriarch. In 1690 Patriarch Arsen Crnojević (Arsenius III) escaped with about 37,000 Serbian families into the Austrian territory. Emperor Leopold I granted them political and ecclesiastical autonomy. Thus arose the Karlovci patriarchate in southern Hungary (Banat).

The Serbian War of Independence broke out in 1804 and resulted in 1830 in the recognition of Prince Miloš Obrenović as the hereditary ruler, subject to the sultan's suzereignty. Two years later the Serbian Church won a conditional autonomy. It was not until 1879 that it became fully autocephalous, after Serbia secured political independence (1876).

Besides these two churches, there existed the Serbian metropolitanate in Bosnia-Herzegovina, which was freed from the jurisdiction of Constantinople in 1880, when the territory became part of Austria-Hungary. Another ecclesiastical unit within the Austrian empire was the metropolitanate of Czernowitz in Bukovina, with which were united the Dalmatian bishoprics of Zara and Kotor. Lastly, the metropolitanate of Montenegro was likewise an independent Serbian church.

Bulgarian Church.—Bulgaria was converted to Christianity in 864 when Tsar Boris was baptized by Byzantine emissaries of Patriarch Photius. The Bulgarian Church became a patriarchate in 917 during the glorious reign of Tsar Simeon. But the Byzantine emperor Basil II put an end to the independence of Bulgaria in 1018, and the Bulgarian Church was reduced to the rank of an archbishopric. Moreover, the see was gradually Hellenized by Greek appointees. In 1186 Bulgarians revolted and established the second Bulgarian empire. The church recovered the patriarchal rank in 1235. Unfortunately, the Turkish victory over the Balkan allies in 1389 put an end to the political independence of the Bulgars for the next five centuries. In 1767 the ancient patriarchate of Ohrid was abolished altogether and the Bulgarian Church subjected to the harsh rule of the ecumenical patriarchate. It did not regain its autonomy until 1870 when the Turkish sultan granted it against the strenuous objections of the ecumenical patriarch. In consequence, there occurred a schism between the Greek churches and the Bulgarian exarchate which was not terminated until 1945.

Rumanian Church.—The Rumanian Church had its origin in the principality of Ugro-Walachia and was at first subject to the Ohrid archbishopric. But in 1359 it passed under the jurisdiction of the ecumenical patriarchate. In Moldavia the first Orthodox episcopal see was organized in the reign of Voivode Peter Musat (1375–91) and acknowledged the supreme jurisdiction of Con-

stantinople (1401). When both these principalities were conquered by the Turks, the two metropolitanates retained a considerable measure of autonomy. But when the Rumanians supported the Russian Peter the Great in his war with Turkey, the latter, upon defeating Peter, imposed upon the Rumanians a harsh rule. The Greek Phanariots then became powerful both in state and church.

As in the other Balkan countries (with the exception of Bulgaria), the independence of the Rumanian Church followed upon the political liberation of the country. In 1858 the autonomy of the two principalities was recognized under a general all-European protectorate. Thereupon, Walachia and Moldavia united to form Rumania. In 1865 the Rumanian Orthodox Church was declared independent of all foreign ecclesiastical rule, but in reality a certain degree of dependence upon the ecumenical patriarchate continued. When Rumania proclaimed itself a kingdom in 1881, the church at last threw off the last vestiges of dependence (1882).

AFTER WORLD WAR I

At the conclusion of World War I, the situation of the Orthodox Churches was greatly changed. For a time, the previous balance of power was radically upset. This was caused by the tragic eclipse of the Russian Church, which had hitherto been the most numerous and powerful (comprising about 110,000,000 members) and the consequent shift of hegemony to the Balkan churches. The victorious soviets as early as Jan. 1918 enacted fundamental ecclesiastical legislation separating the church from the state and from the school. All property, including ecclesiastical possessions, was nationalized. All subsidies ceased. Although in theory full liberty of conscience was granted, in practice the church was treated as the bulwark of the old order and suffered accordingly. Clergy were disfranchized and deprived of the possibility of securing livelihood except by voluntary support of the impoverished congregations. Free use of church buildings was permitted, but later such staggering charges for insurance and other purposes were imposed that many congregations were unable to retain the use of the buildings. All organized teaching of religion to children and youth was forbidden.

Patriarch Tikhon, elected by the sobor of 1917 which had abolished the Holy Governing synod and restored the patriarchate, protested against the spoliation of the church and other inimical acts. He was arrested but a year later was released after he had signed a "confession" promising not to interfere with the new political orientation. In the meantime, there arose schisms within the church, aided and abetted by the government. In 1929 the constitution of the Russian Soviet Federated Socialist Republic reserved the right of "propaganda" only to the antireligious forces and granted to the religious bodies the mere right of "confession." The congregations were restricted to bare liturgical services. Many churches were closed. By the adoption of the five-day week attendance on church services was made extremely difficult. Clergy were singled out for particularly harsh treatment; lay members were discriminated against; children were subjected to antireligious school training. The government went all out for every form of antireligious propaganda.

But all these measures proved inadequate. After the government became aware of the failure of its policy, and at the same time recognized that the church offered no political opposition, it inaugurated a new religious policy in Jan. 1939. Efforts to liquidate religion were discontinued. Antireligious periodicals were restricted or withdrawn. The seven-day week was restored. Many churches were reopened. Even some new ones were built. Group religious instruction was permitted in private. Seminaries for the education of clergy were allowed. In 1946 a theological academy was opened in Moscow. In 1943 the national council for the election of a new patriarch was held, and Metropolitan Sergei was chosen for the post. This was done with the approval of Marshal Joseph Stalin. After Sergei's death, Metropolitan Alexei was raised to the patriarchal throne (1945). The government established two offices for the supervision of religious affairs. Thus, a direct relationship between the church and the state was re-established. In Aug. 1945 the church was recognized as possessing corporate juridical rights. It was officially reported in 1946 that there existed at the time 65 fully constituted dioceses within the U.S.S.R. (10 others abroad), but there were only 59 bishops to serve them. There were about 25,000 parishes, as against 4,225 in 1941. Of the total 46,457 church buildings which had been in existence in 1917, about 57% were in religious use in 1946.

The Balkan churches, during the eclipse of the Russian Church, became the dominant Orthodox bodies. Numerically the largest among them, Rumania, which more than doubled its territory after World War I, consolidated four formerly autocephalous organizations into one, 13,000,000 strong. These four bodies comprised the churches of the old kingdom of Rumania, Transylvania, Bukovina and Bessarabia. In 1925 the process of consolidation was completed. The new constitution proclaimed the Orthodox Church the dominant body, while the Uniates were granted "priority among the cults." The rank of the church was raised to that of patriarchate.

As the result of World War II, Rumania lost Bessarabia and Bukovina; but Transylvania, which had been awarded to Hungary by Adolf Hitler, was restored to Rumania. The postwar government, which was under communist influence, had not by early 1947 made radical changes in the ecclesiastical situation.

The Serbian Orthodox Church was likewise consolidated after World War I in keeping with the great territorial expansion of the kingdom. The six formerly independent ecclesiastical units—metropolitanate of Serbia, patriarchate of Karlovci, Bosnia-Herzegovina, Montenegro, the Dalmatian eparchy and the newly acquired Macedonia—were consolidated into the national Serbian Orthodox Church. The ancient patriarchate of Pech was revived (1920), and the metropolitan of Belgrade, Demetrije, was elected the first occupant of the see.

True to the traditional close relationship between the church and the state, Patriarch Gavrilo (1937–) was influential in the coup d'état which placed young King Peter II on the throne in order to nullify the pact with the Germans which had been negotiated by the regent, Prince Paul. When the nazis invaded Yugoslavia (1941), Gavrilo was imprisoned and later sent to a German concentration camp. He returned to resume his office late in 1946.

In the meantime, Marshal Tito (Josip Brozovich) subjected the country to a totalitarian communist regime. He introduced most radical changes in the status of the Orthodox Church. Church and state were separated. Ecclesiastical property was nationalized. All financial support was withdrawn. Antireligious propaganda was legalized. Compulsory civil marriage legislation was passed. Religious instruction in schools was made optional. Even the territory under the jurisdiction of the Serbian patriarch was reduced in size by the creation of an autonomous Macedonian Church.

Similar radical changes occurred in the Bulgarian Orthodox Church, which in 1945 was restored to communion with the Greek churches. Thereupon, the metropolitan of Sophia, Stephan, was elected exarch (an office which had been vacant from the death of Exarch Joseph, who died in 1915). The country fell under communist domination and in 1946 established a republic. It was planned to separate the church and state. Some of the property of the church had already been nationalized, and the church was faced with the problem of support. A new constitution, which was expected to democratize the administration of the church, was in the process of preparation. The church was forbidden to engage in any social or benevolent service. Religious instruction in schools was suppressed, although it was allowed in private.

The Greek family of Orthodox churches comprises the Church of Greece; the patriarchates of Constantinople, Alexandria and Jerusalem; the Church of Cyprus; the Dodecanese Islands; and Mount Sinai. The Church of Greece, which was constituted in 1833, after Greece had secured political independence from Turkey, did not gain the recognition of the ecumenical patriarchate until 1850. There has always existed a close relation between the Greek Church and the government so that political changes

usually were reflected in the ecclesiastical sphere. Under Eleutherios Venizelos, during World War I, the royalist archbishop Theocletos lost his post to the liberal metropolitan Meletios. But when in 1920 the political situation was reversed and King Constantine regained his throne, Theocletos likewise was restored to the see of Athens.

During and after World War II, the archbishop of Athens, Damaskinos, exercised great political influence. Although not subservient to the German masters during their occupation of Greece, he escaped being deposed by them as his predecessor, Archbishop Chrysanthos, had been. After the country's liberation, Damaskinos became the regent of Greece and retained the office until the recall of King George II to the throne in 1946.

The patriarchate of Constantinople suffered greater and more lasting damage as the result of World War I than any other Orthodox Church. When the nationalist armies under Mustafa Kemal Pasha gained victory over the invading Greek forces under King Constantine, Mustafa at first intended to abolish the ecumenical patriarchate altogether, for Patriarch Meletios had openly sided with King Constantine. But the British, at the Lausanne conference (1923), persuaded him to moderate his plan. Thereupon Mustafa expelled Meletios and stripped the patriarchal office of all but the strictly ecclesiastical functions. Later, by the exchange of population between Turkey and Greece, 1,500,000 Greeks were forced to leave the country. The patriarchate which in 1914 numbered 1,800,000 members, was reduced to 300,000 Greek residents of Constantinople and the immediate environs. In early 1947 the membership was estimated at 100,000. Nevertheless, the ecumenical patriarch still held the pre-eminence of honour among his peers and exercised jurisdiction among the Orthodox in the dispersion.

The number of autocephalous or autonomous Orthodox Churches after World War I was 21. Since then, the patriarchate of Moscow secured the subjection to its authority of the churches of Estonia, Finland and Czechoslovakia. The churches of Lithuania, Latvia and Poland were perhaps likewise absorbed by the Moscow patriarchate, but an official statement to that effect had not been made by 1950. The total number of Eastern Orthodox Churches therefore was reduced accordingly. The Uniate Church of Western Ukrainia renounced its allegiance to the pope in 1946 and re-entered orthodoxy. The small Czechoslovak Orthodox Church suffered greatly during the nazi occupation of the country because the parachutists who had killed the notorious "protector" of Czechoslovakia, Reinhard Heydrich, had taken refuge in the Prague Orthodox church, Bishop Gorazd-Pavlik and the parish priest were put to death. Moreover, the entire organization of the Orthodox Church was dissolved. After the liberation of Czechoslovakia the Orthodox Church in that country was reconstituted. The Albanian Church was also weak after World War II, having been subjected to much hostile treatment on the part of the Italians.

THE EASTERN ORTHODOX CHURCHES IN AMERICA

The beginnings of the Russian settlement of the Aleutian Islands and of Alaska go back to the expedition under the command of Capt. Vitus Bering and Capt. Alexei Chirikov. The latter sighted the territory of Alaska on July 15, 1741. Five days later Captain Bering landed on Kayak Island, where he soon afterward died and was buried. The first Russian to baptize some natives was a Cossack, Andreyan Tolstykh, on the islands bearing his name—the Andreanof Islands (1743). In 1759 a Russian merchant, Ivan Glotov, was the first preacher of Christianity to the Aleutians. He baptized the son of a native "toen" or chieftain of the territory of Umnak. Later he took the young man to Kamchatka where the neophyte, named Ivan after Glotov, learned Russian.

Upon his return, he became a chieftain and was active in spreading Christianity. In 1774 Grigori Ivanovich Shelekhov is said to have baptized 40 natives of Kodiak Island. It was he who organized the first permanent commercial settlement on Kodiak, the Shelekhov-Golikov company. It was named Three Saints, after the ship which had brought Shelekhov to the Aleutians. In 1787 Shelekhov returned to St. Petersburg and laid before Empress Catherine II his plans for the commercial exploitation of the northeastern coast of America. The empress sent an Englishman, Joseph Billings, who had visited Alaska, on a tour of exploration. He arrived at Three Saints on June 20, 1790, and apparently found conditions sufficiently promising to report favourably to Catherine. Shelekhov also urged the empress to send missionaries to Kodiak and promised to assume, with his associate, the payment of their travelling expenses as well as their support.

Thereupon, Alexander A. Baranof, a merchant of Kargopol, was appointed manager of the colony. Under his energetic leadership the colony became a powerful factor in the development of the territory. He transferred the headquarters to the northeast part of the island and named the new settlement Paul's Harbor in honour of the heir to the throne, Grand Duke Paul. He likewise requested the home management for priests to evangelize the natives as well as to serve the religious needs of the Russians.

Such a mission, headed by the archimandrite Joasaph Bogolov, who was accompanied by seven monks, arrived in Sept. 1794. The trip lasted ten months. The missionaries came from the Valaam monastery on Lake Lagoda. Along with them arrived 150 administrators and 30 families of settlers. This group laid the foundations of Russian orthodoxy in America. Within two months of their arrival, two of their number, hieromonks Macarius and Juvenal, travelled over the whole island and baptized about 6,000 natives (another account says "all the inhabitants"). The letters of some of these earliest missionaries are extant. They were written to the hegumenos of the home monastery of Valaam. German, for instance, wrote: "The Aleuts greatly surprised us by their dexterity and desire to be baptized." Another monk, Joasaph, wrote: "On Kodiak almost 6,000 were baptized. They accepted the baptism so sincerely that they broke all their shaman paraphernalia and burned it." But "the apostle of the Aleuts," Bishop Innocent, writing more than 50 years later, complained that Kodiak natives were still half pagan, adhering to their shaman practices, although the Unalaska Aleuts persevered sincerely in their Christianity. During the winter of 1794 the missionaries established the first Russian church and school at Paul's Harbor and consecrated it to the Resurrection of Our Lord. It was destroyed by fire in 1943.

The next spring they extended their missionary labours to other Aleutian islands and within two years claimed to have baptized 12,000 natives and to have built a church or chapel "in every more or less important" community. In 1795 Juvenal left Kodiak for Nuchen and Kenai bay and the following year went to the Alaskan mainland. It is not clear how far north he penetrated, but he met his death near the Iliamna lake. He had persuaded some chieftains to entrust him with their children so that he might educate them; but later they changed their minds, perhaps because he had prohibited polygamy, and after a pursuit caught up with him and killed him as "a deceiver."

The commercial company prospered so well that Emperor Paul I enlarged it by combining the Shelekhov-Golikov company with the Mylnikov company, renaming the new organization the Russian-American company. It was under obligation to provide for the religious needs of the colonists as well as of the natives. Shelekhov, who then lived in Russia, was not satisfied with the progress of the missionary work. He estimated the number of inhabitants of Kodiak Island at 50,000, of whom only about 6,000 had been baptized. It is possible that Shelekhov's estimate refers to all the natives of the Aleutian Islands and Alaska; but Bishop Innocent, who mentions it twice, plainly applies it to Kodiak alone. At any rate, Shelekhov now urged the authorities to establish an episcopal see for Russian America. In 1799 the Holy synod, heeding this request, raised the archimandrite Joasaph to the episcopal rank. The new diocese comprised Kodiak, Kamchatka and Alaska. Unfortunately, the new bishop, upon his return from Irkutsk, Siberia, where he had received consecration, was drowned when his ship foundered off Kodiak Island. Thereupon, the see remained vacant for 40 years.

Nineteenth Century.—For the next 17 years, the work of evangelization was largely at a standstill. Shelekhov died in 1800. Only three members of the original mission were left: of these, Athanasius alone was at Kodiak. German outlived the rest, having retired as a hermit to Spruce Island, where he lived in a cave, although he carried on some work of teaching and preaching. He remained there 40 years, dying in his 81st year in 1837. It was not until 1816 that an additional priest, Alexei Sokolov, was sent to join the depleted staff.

Between 1808 and 1816 the success of the Russian-American company was gratifying. Baranov transferred the headquarters from Kodiak to Baranov Island, where Sitka was chosen as the new capital.

A MANUAL OF THE SACRED VESTMENTS AS USED IN THE HOLY ORTHODOX CHURCH IN AMERICA

1. Robe (*riassa*); 2. Sticharion; 3. Orarion; 4. Zone (girdle); 5. Cuffs; 6. Stole; 7. Phelonion (chasuble); 8. Epigonation; 9. Thigh Shield; 10. Eagle rug; 11. Saccos and the omophorion; 12. Kamalavka; 13. Crown; 14. Panagia; 15. Crozier; 16. Cross; 17. Bishop's mantle

The natives, Koloshi, were different from the meek and friendly Aleuts. They looked upon the Russians "as their terrible enemies, and only bided their time when they could drive them out," as Father Venyaminov (who later became Bishop Innocent) reported. To deal with them, Baranov requested the Holy synod to send him missionaries. He also established a settlement in California, calling it Ross; but this colonization venture did not succeed. At the time Father Venyaminov visited the place in 1838, there were 216 colonists composed of Russians, Aleuts and those of mixed parentage, besides 39 Indians. In 1841 the land was sold by the Russian government to a certain Mr. Sutter for $30,000.

In 1821 the government gave the company a new charter. This document stipulated that the company must provide adequately for the religious needs of the settlers. Thus spurred, the company requested the Holy synod to send them more missionaries. The latter turned to the bishop of Irkutsk with the request that he provide them, but the bishop could find no volunteers. At last a local priest, Father John Venyaminov, offered himself, having learned of the conditions at Unalaska from a colonist Ivan Kryukov who had recently returned from the island after having lived 40 years among the Aleuts. In 1823 Father John moved with his whole family—consisting of his widowed mother, his wife and one-year-old son—to Unalaska. He took a boat to Yakutsk and then travelled on horseback to Okhotsk, about 700 mi. away. From there he took a sailing boat to Unalaska. He arrived there on July 29, 1824. His parish included not only Unalaska, but also other Fox and Pribilov Islands. He lived in an earthen hut but later built himself a wooden house. Having found only one frame chapel on Unalaska, he undertook, first of all, to build a new church. Upon its completion he dedicated it to the Ascension of the Lord. His sermons preached to the natives are still extant and are not exactly "milk for babes."

The zealous young priest—he was only 27 at the time of his arrival—soon extended his missionary efforts to other islands, spending the greater part of the year in sailing in his "haidarka" from island to island. Two other priests who had come about the same time, Father Frumentius Mordovsky and Jacob Netsvyetov, worked at Kodiak and Atlaha.

Father John soon learned the native languages and then composed a primer and translated, with the aid of others, the Gospel of St. Matthew, the catechism and the liturgical books. In order to reduce the language to the written form, he had to invent an appropriate alphabet. After spending ten years in such fruitful labours at Unalaska, he was transferred to the port of New Archangel, or Sitka. There he had to begin his missionary and linguistic labours anew, for there he worked among the Kolosh tribe belonging to the Thlinket Indians. The work among them was much more difficult than that done previously among the Aleuts. Nevertheless, it was crowned with considerable success. Within five years he established schools for native children whom he taught from textbooks of his own composition. He likewise taught them trades. He even introduced inoculation.

However, the work soon grew so large that he needed help. He left Sitka in 1838 for St. Petersburg "exclusively for the purpose of publishing, under my own supervision, my translation of the holy books into the Aleut language," as he reports in his autobiographical sketch. While he stayed in the Russian capital, his wife died. Upon the advice of Metropolitan Philaret of Moscow, who greatly admired the intrepid missionary, Father John assumed the monastic habit, adopting the name of Innocent on this occasion. He was made an archimandrite. Soon after, the Holy synod chose him for the episcopal see vacant after the drowning of Bishop Joasaph in 1799. He was consecrated on Dec. 15, 1840, in the Kazan cathedral in St. Petersburg. Ten months later he was back in Sitka.

Upon his return, Bishop Innocent ordained several priests and in 1842 began extensive episcopal visitation, which he described with minute detail in his *Diary*. This is a mine of information concerning the condition of the churches. He built the cathedral church of St. Michael in Sitka, which was consecrated in 1848 and which still stands. Also he founded a missionary school and a seminary for the training of the native priesthood. His diocese was enormous, comprising not only the colonies in America, but also Okhotsk and Kamchatka. He travelled on dog sleds, often in temperatures of 20° below zero. His energy and zeal were inexhaustible. For his truly great labours he was made archbishop in 1850.

But this was not the end of his career. The holy synod further enlarged his diocese by adding Yakutsk in Siberia to the already enormous territory under his care. The archbishop was obliged to transfer his residence from Sitka to Yakutsk. Thereupon, in 1857, he was granted the aid of two vicars, one for Sitka and the other for Yakutsk. When the famous metropolitan Philaret of Moscow died in 1867, it was the intrepid missionary to the Aleuts and the Koloshi, Archbishop Innocent, who succeeded him. He died in 1879.

The period just described came to an abrupt termination when the United States government purchased Alaska from Russia in 1867. The sum paid for it was $7,200,000. Since many Russian settlers thereafter left the country and the Russian government lost interest in those who remained, the missionary work declined. At that time the membership of the Sitka diocese was in excess of 12,000. Archbishop Innocent had secured, at the time of the sale, the incorporation of a clause guaranteeing the property and rights of the Russian Orthodox Church so that missionary work could be continued. Innocent appointed Bishop Paul to serve the Alaska diocese. His term of service lasted from 1867 to 1870. During this time, Protestant and Catholic missionaries entered Alaska. When it became apparent that more aggressive methods were needed to conserve the gains made by the Russian Church, a new bishop was sent out to replace the non-aggressive Paul.

Such a person was found in Bishop John who was consecrated "Bishop of the Aleutian Islands and Alaska." He was a scholar and a church historian who published a five-volume work on the history of American Christianity. In 1872 he moved the episcopal see to San Francisco, Calif. A beginning of the Russian, Serbian and Greek colony near San Francisco was made at Ross, the ancient Russian settlement abandoned in 1841. When gold was found in the vicinity, fortune hunters of all nations, including the above-mentioned Orthodox nationals, were attracted to the place. But Bishop John was recalled to Russia in 1876 and three years later was succeeded by Bishop Nestor.

Under Bishop Nicholas (1891–98) the diocese was enlarged by the inclusion of Canada and the eastern states of the Atlantic seacoast. Moreover, his predecessor, Bishop Vladimir, had succeeded in extending his jurisdiction over the Uniate Ruthenians (or Carpatho-Russians), who had repudiated the Roman Catholic jurisdiction and returned to orthodoxy.

During the 1880s, Russian immigration increased greatly. Likewise, other Orthodox immigrants, such as Bulgarians, Rumanians and Albanians, settled in the east and the middle west in large numbers. In such manner, the centre of gravity shifted to the east. Consequently, in 1898 Bishop Tikhon, who had succeeded Nicholas in 1898, transferred the see once more, this time to New York city, where the first Russian parish had been organized 35 years previously.

Twentieth Century.—In 1901 St. Nicholas cathedral was founded. The rank of the American hierarch was raised two years later to that of an archbishop. Moreover, Tikhon was assisted in the administration of his enormous archdiocese by two vicar bishops: Innocent for the diocese of Alaska, and Raphael for the Syrian diocese. The latter, though a Syrian born in Damascus, had been educated at the Kazan Theological academy and had been brought to America, along with two other Syrian as well as many Russian priests, by Bishop Nicholas. Later, two other bishoprics were founded—one in Pittsburgh, Pa., and another in Canada. In 1905 the Orthodox Theological seminary opened its doors, and the following year the first Russian monastery was founded. By 1916 there were 343 Orthodox churches, comprising 465,000 members under the jurisdiction of the Russian archbishop.

Tikhon, like his illustrious predecessor in the first half of the 19th century, Archbishop Innocent, attained to the high dignity of the metropolitan of Moscow. In fact, he rose to the highest post in the gift of his church, the patriarchate. When in 1917 the patriarchal office, abolished by Peter the Great, was restored, Metropolitan Tikhon was elected its first occupant.

The bolshevist revolution of 1917 had a disastrous effect upon the dominant position of the Russian Church in America as well as at home. For the hegemony of the Russians among the other Orthodox communions in America was utterly shattered, and the American Russian archdiocese itself suffered disorganization. Archbishop Evdokim (1914–17), who ruled the archdiocese at the time of the downfall of the tsarist regime, returned to Russia in 1917 to attend the All-Russian Territorial council held in Moscow. Since, however, his sympathies turned prorevolutionary, and he joined the Living Church group, it appeared that he would not return to his American see. One of the suffragan bishops left in charge of the administration in America took steps to terminate the anomalous situation thus created. This was Bishop Alexander (Nemolovsky) of Canada, who in 1919 called an All-American convention to meet at Pittsburgh, Pa. This body declared the Russian Church in America "temporarily autonomous," although within the framework of the dogmatic, canonical and liturgical system of eastern orthodoxy. Furthermore, it elected Alexander the archbishop of the new organization. Henceforth, this body assumed the name the Russian Orthodox Church of North America. In this fashion, a new era of the life of the American Russian Church was begun. The action was taken in line with the policy of Patriarch Tikhon, who had instructed the bishops under his jurisdiction to conduct the administration of their dioceses independently since for the time being the soviet government did not allow him to carry on his constitutional jurisdiction over them. Despite the self-governing status, however, the church "did not sever at all the spiritual ties and communion with the Russian church."

But greater troubles were in store. Upon the imprisonment of Patriarch Tikhon in 1922, a group of clergy of the Living Church seized the patriarchal chancery and usurped the supreme administration of the church. In 1923 after they had purged the episcopal ranks of their opponents, they called a council for the reorganization of the church. This revolutionary gathering reversed the political trend of Tikhon's administration by acknowledging the soviet regime, abolished the patriarchate, deprived Patriarch Tikhon of all his authority and functions and reduced him to the status of a layman, instituted married episcopate and adopted other radical reforms. As far as the American archdiocese was concerned, the council appointed as its head the Rev. John Savitz Kedrovsky, then pastor of All Saints' church in Hartford, Conn., and consecrated him to the archiepiscopal rank.

But Patriarch Tikhon, although in prison, did not cease to exercise his patriarchal functions. In 1922 by a verbal order (since he was prevented from putting it in writing) he appointed Metropolitan Platon, then of Kherson and Odessa, but formerly of the American archdiocese (1907–14), as the head of the Russian Church in America. He was acknowledged as such by the convention held in Detroit, Mich., in 1924 and retained the office until his death in 1934. Archbishop Alexander left for Russia and during World War II was killed by the nazis. Naturally, a struggle ensued between Platon and Kedrovsky. The latter appealed to civil courts to decide the jurisdictional dispute. In the end, the court decided in favour of Archbishop Kedrovsky, who thereupon was awarded the possession of the Cathedral of St. Nicholas and the archiepiscopal residence. The congregation of St. Nicholas, however, followed Archbishop Platon to a temporary home offered them by the Trinity Episcopal Church.

In the meantime, the Russian Orthodox Church under the leadership of Metropolitan Sergei made its peace with the soviet regime sufficiently to make it possible for him to carry on its administration. In 1933 Sergei dispatched to America Bishop Benjamin as his exarch. The latter demanded not only submission of the American churches to his jurisdiction but also a pledge of loyalty to the soviet government. When this pledge was refused, Sergei laid the American church under suspension, without any formal trial.

After Platon's death, Bishop Theophilus of San Francisco was elected to the vacant see by the convention of Cleveland, held on Nov. 21, 1934. He had come to America in 1891 in the suite of Bishop Nicholas so that he brought to his archiepiscopal task long experience in the American service. The new archbishop visited Patriarch Barnabas of Serbia in 1935 and negotiated an agreement with the Karlovci synod, which claimed jurisdiction over the Russians outside the U.S.S.R. in opposition to the Moscow patriarchate. Two years after his return, Archbishop Theophilus called a convention which met in New York city on Oct. 5–8, 1937, and approved the reorganization of the administration. The most important change then instituted was that the so-called Metropolitan council was set up as the permanent executive body. It is composed of both lay and clerical members and acts with the approval of the metropolitan (which title was conferred upon Theophilus).

In the meantime, an astonishing *volte-face* in the religious policy of the soviet government brought about a great improvement in the outward condition of the Russian Church. An All-Russian council for the election of the patriarch was permitted in 1943; and the *locum tenens,* Metropolitan Sergei, was chosen for that office, the duties of which he had so long performed. However, he died the next year, and on Feb. 2, 1945, Metropolitan Alexei was elected to succeed him. On this occasion, and despite the sentence of suspension still in force, the American metropolitanate received an invitation to be represented at the council. Four delegates were chosen for this purpose, but only three received visas. Furthermore, because of transportation difficulties, the delegates arrived ten days after the conclusion of the council. Nevertheless, they presented their case to Patriarch Alexei, intimating the desire of the American metropolitanate for a renewal of canonical intercourse with the Moscow patriarchate. The patriarch, a few days later, replied in his *Ukaz* of Feb. 16, in which he laid down the following conditions: a new delimitation of the territory of the American metropolitanate; a council was to be called for the settlement of the outstanding issues, to be presided over by the patriarch's representative, Archbishop Alexei of Yaroslav and Rostov; this council must renounce, in behalf of the American Russian Church, all political activities against the soviet government; and it was to elect a new metropolitan; for this office the patriarch recommended Metropolitan Benjamin or Archbishop Alexei, although he permitted the council "to nominate and elect its own candidate"; nevertheless, the patriarch reserved for himself "the right to refuse confirmation of the chosen candidate if considered unsuitable for any motivated reasons whatsoever." Besides, the patriarch reserved to himself the rights of hearing appeals from American bishops and clergy and of confirming all episcopal appointments.

The American Bishops' council met in Chicago, Ill., on May 22–24 and carefully considered the patriarchal *Ukaz.* The conditions laid down in that document were carefully scrutinized and declared unacceptable on the ground that the autonomy of the American church must be retained. The Russian Church in America "is an American church and an American church it must continue to be." American citizens cannot be ordered by their ecclesiastical superiors what political views they should accept or reject. Nevertheless, this decision did not altogether terminate the negotiations.

The loss of Russian hegemony among the American Orthodox resulted, or greatly aided, in the organization of independent Orthodox churches among the various non-Russian nationalities. Among them, the largest Orthodox Church in the United States was the Greek, comprising, according to the U.S. census of 1936, almost 190,000 members. The earliest Greek Church in the United States was organized in New Orleans, La., in 1867. As the Greek immigration increased, Greek Churches were organized in many American cities. They were left, however, without episcopal supervision by the patriarchate of Constantinople or the Holy synod of Greece, to which bodies they were, in a loose fashion, related. In order to remedy this situation, the patriarchate of Constantinople in 1908 assigned its jurisdiction over American Greeks to the Holy synod of Greece, with the understanding that the latter was to organize the Greek Churches in America into a diocese.

But the actual realization of this plan was delayed another ten years. At last in 1918 the archbishop of Athens, Meletios Metaxakis,

came to the United States with the intention of setting up a Hellenic diocese. But soon he realized that the time was not yet ripe for such an action. Accordingly, he created a synodical trusteeship and placed Bishop Alexander of Rodostolos in charge.

However, soon after his return to Athens, Archbishop Meletios was deposed because of the radical political upheaval which had occurred; in 1920 Venizelos was displaced by King Constantine. The latter signalized his resumption of office by a correspondingly radical change in the ecclesiastical policy. The reverberations of this upheaval were felt even in America, for Bishop Alexander was likewise deposed by the Holy Synod, along with Archbishop Meletios. In his place a synodical exarch, in the person of Bishop Germanos of Sparta, was sent to the United States.

But the deposed Archbishop Meletios was elected in 1921 to the vacant see of the patriarchate of Constantinople. The next year he issued the so-called Founding tome, whereby he rescinded the tome of 1908, giving the synod of Greece jurisdiction over America, and assumed that jurisdiction himself. He sent Bishop Alexander back to his former charge but with the rank of archbishop of North and South America. Unfortunately, an influential royalist faction among the American Greeks refused to acknowledge him and gave support to Metropolitan Basil, whom they had invited to America in the meantime.

The confused situation remained essentially unchanged until the arrival of Metropolitan Damascenos of Corinth; he came to America in 1928 in order to raise money. Upon his return to Greece, he reported to the patriarch the sad state of American affairs. The latter empowered him to return to America and to bring order out of the existing chaos. In order to accomplish this laudable object, both Alexander and Basil were recalled, along with all American bishops. Damascenos arrived in America in 1930 and succeeded in the difficult task of uniting the existing rival factions into the newly created ecumenical province. The man chosen to head the new archdiocese was Metropolitan Athenagoras of Corfu, who as archbishop of the Greek Orthodox Church (Hellenic) held sway over all American Greek Churches.

The remaining Orthodox communions in America are numerically smaller than the Greek and the Russian. Although the numerical relationship and proportion of these communions has perhaps changed since 1936, for which year the U.S. census reports them, it is the statistical basis given in this official publication which has been followed. The Serbian Orthodox Church, which prior to 1921 was under the Russian jurisdiction, organized itself separately in that year. The first Serbian Church in the United States was gathered in 1894 by the Rev. Sebastian Dabovich in Jackson, Calif., and he became its first pastor. He was born in San Francisco and was educated for the priesthood in his native city and in St. Petersburg, Russia. He died in 1940 in the famous historic Serbian monastery of Zicha and is buried there.

In 1921 it was thought advisable to organize the Serbian Churches in America into an independent diocese. The Serbian patriarchate appointed in 1927, as the first bishop of America, the first hegumenos of the Serbian monastery of St. Sava, which is located near Libertyville, Ill., the archimandrite Mardary Uskokovich.

The Syrian Antiochian Orthodox Church established its independent organization in 1927. Originally, the Syrians were ecclesiastically subject to the Russian archbishop, who had raised their mission to the rank of a diocese in 1905, at which time he had appointed the archimandrite Raphael Gavanini as its first bishop. Ten years later Bishop Raphael was succeeded by Bishop Aftimios, who continued in canonical obedience of the Russian Church until 1927, when he withdrew. Later, when he married, he was excommunicated. Thereupon, the Syrian parishes divided into five groups, each acknowledging a different bishop. Some of the bishops died, others were excommunicated. In order to unify the American parishes under one jurisdiction, the Antiochene patriarch in 1934 appointed the archimandrite Antony Bashir as his vicar and charged him with the task of setting up the Syrian Antiochian Orthodox archdiocese. Two years later, at the request of the archdiocese, Archimandrite Bashir was consecrated by the patriarch of Antioch as the first Syrian archbishop of New York and of all North America.

The Rumanian Orthodox Missionary Episcopate in America goes back to 1918 for its organization. At that time there was a sufficient number of churches in existence to form a diocese. The earliest of these was organized in 1905 in Cleveland, O. In 1918 Bishop Policarp Morusca arrived in the United States with the purpose of uniting the scattered congregations into the first Rumanian episcopal diocese with headquarters in Youngstown, O. But in 1929 the general congress which met in Detroit, Mich., decided to move the headquarters to Grass Lakes, Mich., although this was not actually accomplished until Dec. 1943. The president of the Episcopal council, the Very Rev. S. Mihaltian, reported the number of communicants in 1947 as numbering 80,000, although the census of 1936 gives only a little more than 15,000.

The Ukrainian Orthodox Church of America was recruited from among the Uniates. These immigrants became greatly dissatisfied with the American Roman Catholic hierarchy because the latter objected to the Uniate married priesthood, suspended many Ukrainian priests and in general tried to Latinize them. In the end, the Rev. Dr. Alexis G. Toth of Minneapolis, Minn., went over to the jurisdiction of the Russian bishop Vladimir. This occurred in 1891. He was quickly followed by other Ukrainian priests and congregations.

But many Ukrainians did not favour this method of solving their difficulties for they disliked the Russian jurisdiction as much as the Roman Catholic. In 1927 they cut themselves off from the latter and established an independent Ukrainian Orthodox Church in America. At first they elected an administrator to conduct the new organization In 1930 Dr. Joseph Zuk was chosen for this office. Under his leadership, the Ukrainian Church submitted to the jurisdiction of the ecumenical patriarch, whose authority was preferred to that of the Russian hierarchy. Dr. Zuk was then consecrated bishop. But he died in 1934 and was succeeded three years later by Bishop Bohdan. The latter was consecrated by Archbishop Athenagoras, the ranking hierarch of the patriarchate of Constantinople in America. But otherwise the Ukrainian Church is administratively quite independent of the Greek archdiocese.

A group closely related racially to the Ukrainian Orthodox Church is the Carpatho-Russian Greek Catholic Diocese of Orthodox Christian Church, U.S.A., for it comprises the Ruthenians from Sub-Carpathian Ruthenia. Uniatism had been imposed on these originally Orthodox people, just as had been the case with the Ukrainians. As has already been mentioned, after 1891 many of these people submitted to the jurisdiction of the Russian Church in the United States. Their numbers were so considerable, that in 1916 the Russian archbishop Evdokim consecrated the Rev. Stephen Dziubay bishop for their parishes. But during the troubles in which the Russian Church became involved after 1917, both in America and abroad, the Ruthenians became dissatisfied. Thereupon, Bishop Dziubay withdrew from the jurisdiction of Metropolitan Platon and decided to lead his flock back into submission to the Roman Catholic Church. But in this plan he was opposed by many of his own people for whom Catholicism was as distasteful as the Russian Church. This group secured the leadership of the Canadian Ruthenian bishop, Adam Philipovsky, who decided to establish an independent Ruthenian Orthodox Church. In this project he was naturally opposed by Metropolitan Platon, who fought against such diminution of his archdiocese on the ground that no separate ecclesiastical jurisdiction should exist for Ruthenians, who are but a branch of the Russian Church. Both parties appealed the case to the Karlovci synod in Yugoslavia. This body decided in favour of Bishop Adam. Accordingly, in 1931 he organized the North American Russian Orthodox Greek Catholic diocese. It is interesting to note that although this group had renounced Uniatism and became Orthodox, yet it retained in its title the phrase "Greek Catholic" which is the usual designation for the Slavic Uniates. Nevertheless, although an attempt was made on the part of the Roman Catholic authorities to restrain them from the use of the term, the court decided in their favour. In 1935 Bishop Adam was raised to the rank of archbishop.

In the meantime, the group which had followed Bishop Dziubay into affiliation with the Roman Catholic Church soon grew dissatisfied with the new arrangement. Many churches repudiated the Roman jurisdiction and sought to effect a separate, independent organization. But for about ten years they were unable to do so, being involved in lawsuits with the Roman Catholic authorities. Finally, in 1937 they declared themselves independent and organized a self-governing body under the cumbersome name of the Russian Greek Catholic Orthodox Diocese of Eastern Rite Church of North and South America. At the same convention they elected the Rev. Orestes P. Chornock as their bishop, and the next year he obtained consecration as such at the hands of the patriarch of Constantinople. Consequently, he was excommunicated by the Roman Catholic Church.

Beside these communions, there exist smaller foreign-language Orthodox bodies in the United States, such as the Albanian and the Bulgarian Orthodox Churches; but their membership is relatively small. In addition, there are in existence three native American Orthodox Churches, the purpose of which is to naturalize eastern orthodoxy among native Americans, give it "a definite place in American life" and integrate it with American Christianity in general. These bodies were organized independently of each other, the oldest among them being the Holy Eastern Catholic and Apostolic Church. Its first congregation was gathered in 1922. Three years later, its first bishop was consecrated in the person of the former Anglican priest, the Rev. Arthur Wolfort Brooks, who assumed the name of Mar John Emmanuel. The consecrator was the Chaldean bishop Mar Antony who was assisted by two other Chaldean bishops.

The second of these communions is the Holy Orthodox Church in America. This body traces its beginnings to the act of the Russian metropolitan Platon, dated Feb. 2, 1927, directing Archbishop Aftimios to establish means and methods whereby Orthodox services would be provided for English-speaking members of parishes or for any "American residents of parishes." The Very Rev. Leonid Turkevich was to be consecrated the first bishop in charge of this work. But for some reason this intention was not carried out. Instead, in 1932 Archbishop Aftimios consecrated the Rev. William A. Nichols as the first bishop of Washington, D.C. He assumed the name of Ignatius. In 1934 the projected American Orthodox Church was organized, and it was incorporated two years later. The liturgical and other services of this church are in English.

The third of these native Orthodox communions is the American Holy Orthodox Catholic Apostolic Eastern Church, which was insti-

tuted in 1932 and incorporated the next year. Three years later the national council of this body created a patriarchate of Washington for the purpose of federating "Christian bodies of other rites who accept or have adopted for themselves the confession of faith of the Orthodox Catholic Eastern Church."

Organization.—Despite the hierarchical organization of the Orthodox Churches, the conduct of ecclesiastical affairs, both locally and on the diocesan and national levels, is quite democratic. Thus, the Russian council which elects the metropolitan is composed of both lay and clerical elements and possesses supreme authority as the governing body. The same is true of the Serbian and Rumanian ecclesiastical organizations; these churches are governed by representative national conventions in which lay members from all local churches and all the priests participate. The Serbian sabor legislates for the church, reviews the work of the local congregations and elects the members of the Diocesan council which is composed of seven priests and nine laymen. The Rumanian Church congress meets annually. Each local congregation sends to it its priest and two laymen so that the lay element predominates. The congress elects the Episcopal council, which consists of four priests and eight laymen, and to which are entrusted the administrative duties. Essentially the same democratic organization, in which the lay membership often is in majority, is characteristic of the other Orthodox communions. An exception to this statement is the Greek archdiocese, which is governed by the archbishop assisted by four bishops. A convention composed of all the clergy and one lay representative from each congregation meets every three years, but its functions are largely advisory.

The most significant characteristic of American orthodoxy is that with the exception of the three native groups, the rest of the communions are aligned with the jurisdiction of their respective mother churches. Their bishops and other hierarchs are usually appointees of the ecclesiastical authorities abroad and often are actually members of such bodies. The chief exception is the Russian Church, which is autonomous. Nevertheless, even in this case a strong effort is made by the patriarch of Moscow to induce it to surrender its autonomy. Accordingly, although the American Orthodox communions are as a rule self-governing, many of them do not possess hierarchical autonomy.

Furthermore, just as there exists such a close bond of union between the American daughter churches and their mother organizations, there is a marked lack of co-operation among the Orthodox bodies in America. Consequently, instead of attempting to solve such common problems as the education of the American-born priesthood, each communion tries to do it separately or depends upon clergy educated abroad. Another consequence of this situation is that every foreign-speaking Orthodox communion attempts to preserve, as far as possible, its native language and culture and opposes by all means possible the assimilation of its members in the American majority. In fact, the church often serves as the chief agency of such a program. The liturgical services are conducted almost exclusively in the language of the respective community—Greek, Rumanian, Syriac or Church Slavonic. There is, accordingly, a need for weekday schools in which the language of the respective group would be taught to the children. In this educational program the Greeks are pre-eminently successful, although the Russians in 1947 reported almost 70% of the total number of their children in the weekday schools. The publication of church periodical literature is largely motivated by the same intent.

The above considerations apply to practically all Orthodox communions, with the exception of the three native American bodies mentioned previously. Although necessarily depending for their orders upon one or another of the ancient eastern Orthodox communions, they aim to make eastern orthodoxy an integral part of American Christianity, to make available to the native American the riches of the faith and cultus of the Christian east and to acquaint western Christendom with the spirit of orthodoxy. This is in line with the ecumenical character of the emerging new Christendom as it takes form in the World Council of Churches. Thus, these communions perform a useful and necessary function of helping the eastern Orthodox nationals in America to become integrated as component elements of American Christianity.

It is, furthermore, the declared purpose of these native Orthodox bodies to foster a broad social and civic outlook in keeping with the modern needs of American life. They emphasize practical, Christian living, the establishment of better human relations, as well as the spiritual aspects of Christianity. The missionary work is not proselytizing in intention and spirit.

ORTHOGENESIS, "straight-line evolution," a term descriptive of the phenomenon in which successive members of an evolutionary series become increasingly modified in a single undeviating direction; the word is further used to designate theories framed to explain such phenomena. Ortho-evolution, ortho-selection, aristogenesis, undeviating evolution, rectilinear evolution are synonymous or related terms. That evolution frequently proceeds in orthogenetic fashion is undeniable. Theodor Eimer, an early exponent of orthogenesis, based his work on butterfly wing venation; fossil invertebrates show many orthogenetic sequences; H. F. Osborn, W. K. Gregory and others have cited numerous examples in vertebrate palaeontology. In some cases the structural changes concerned are obviously adaptive and a Darwinian explanation (ortho-selection) is reasonable. An orthogenetic "family tree" presents the picture of a single straight stem rather than a branching structure; this appearance may be because of the fact that side branches, when begun, were vigorously pruned by natural selection.

In many instances, however, the striking features developed in an orthogenetic phylum appear to have little if any adaptive value and may even be markedly disadvantageous. To explain such cases is more difficult. No genetic evidence has been found (despite search for it) of progressive mutation in a given direction. Various theories have been proposed involving an "inner urge" toward a predestined evolutionary goal or some other mystical or theological concept. But many workers feel that more rational explanations are possible. Recent work in genetics has shown that even very small mutations may have a definite survival value. Further, the action of a gene is not confined to a single character; the growth of disadvantageous structures (as for example the huge antlers of the extinct Irish "elk") may well have been merely unfortunate genetic concomitants of the development of other structural or functional features of great utility.

Related evolutionary phenomena are parallelism and the so-called law of the irreversibility of evolution. Parallel trends are frequently seen in related but distinct evolutionary phyla; these trends are often orthogenetic in pattern. The "law" of irreversibility is based upon the occurrence of orthogenesis. However, there are many known non-orthogenetic evolutionary lines, and there are numerous instances of reversibility. (*See* EVOLUTION, ORGANIC.) (A. S. RR.)

ORTHOPAEDIC SURGERY is that branch of surgery the purposes of which are to prevent and correct deformity and to improve and preserve the functions of the bones, joints and motor apparatus.

History.—The term orthopaedics was given to this specialty in 1741 by Nicholas André, professor of medicine at the University of Paris. The term was synthesized from the Greek roots *orthos* (straight) and *pais* (child). Although the scope of orthopaedic surgery has gone far beyond the prevention and care of deformities in children, the name lasts and seems to be a permanent part of medical nomenclature in spite of sporadic efforts to have the specialty designated by some other term. According to E. M. Bick, the establishment of the first institute for the treatment of skeletal deformities at Orbe, Switzerland, by Jean André Venel, a physician of Geneva, was a milestone in the development of orthopaedic surgery in the 18th century. During the remaining portion of the 18th century, outstanding work in orthopaedic surgery was done by William Hunter, who contributed to our knowledge of the structure of joints, and by John Hunter (1728–93), his younger brother, who contributed to our knowledge of muscular function and bony growth and development. John Hilton (1804–78) exerted a great influence on the development of orthopaedic surgery with his book *On Rest and Pain,* which undoubtedly helped to influence thinking during the long period in which rest was considered to be the most important part of orthopaedic care. G. F. L. Stromeyer (1804–76), a German surgeon of Hanover, developed the operation of tenotomy (cutting of tendons) by which deformities could be more easily corrected. It was to Stromeyer that William J. Little (1810–94), himself a cripple with a paralytic deformed foot, went to have the deformity corrected in 1836. Arthur Keith said that "there can be no doubt that Little was the pioneer of orthopaedic surgery in England." His studies on the causes of clubfoot and his introduction of tenotomy in England were outstanding steps in the development of orthopaedic surgery. Hugh Owen Thomas (1834–91) was one of the outstanding leaders in the development of this specialty. A direct descendant of a long line of bonesetters, he studied medicine in Edinburgh, London and Paris, and practised in Liverpool. Among his more outstanding contributions to orthopaedic surgery was the Thomas splint, which is still widely used in the treatment of fractures of the long bones.

The modern era in the development of orthopaedic surgery usually is regarded as beginning with the work of Sir Robert Jones (1858–1933). His recognition became world-wide during World War I. The organization of the orthopaedic centres and curative workshops was carried out under his direction, and many orthopaedic surgeons, both British and American, came under his influence. The introduction of surgical methods which could be used in conjunction with splinting in the treatment of fractures and severe injuries of the extremities may be ascribed to the period of World War I and to the leadership of Sir Robert Jones.

In the United States the names of L. A. Sayre, Henry G. Davis and Charles F. Taylor are outstanding in New York city, while in Boston, Mass., orthopaedic surgery was developed by John Ball Brown and Buckminster Brown, to be followed by E. H. Bradford, Robert W. Lovett and others.

One of the modern leaders in the development of orthopaedic surgery in the United States was F. H. Albee (1876–1945), whose development of the motor bone saw in 1909 led to an entirely new era in bone-grafting methods which are commonly used in the correction of deformities and disabilities of bones and joints. Robert W. Lovett (1859–1924), a leader in the Boston group, did much to develop knowledge of the care of patients affected with infantile paralysis (anterior poliomyelitis) and also helped to develop knowledge of scoliosis (curvature of the spinal column) and its treatment. Michael Hoke (1874–1944) of Atlanta, Ga., contributed much to the correction of foot deformities and stabilization of joints. Royal Whitman (1857–1946) was an outstanding teacher and orthopaedic surgeon, and Willis Campbell (1880–1941) contributed much to the development of modern orthopaedic methods and technique.

Scope.—In discussing the scope of modern orthopaedic surgery, the prevention of disabilities and deformities, as well as their correction, must be stressed. Orthopaedic surgery may be divided into two parts, preventive and reconstructive. Deformities may be either congenital or acquired. Of the congenital deformities, there are three types: (1) those caused by disturbances in embryologic development and intra-uterine growth; (2) those which are actually inherited and transmitted from generation to generation; and (3) those which are based on evolutionary changes in the human species. Examples of the first group are intra-uterine amputations; examples of the second group are congenital dislocations of the hip and the related condition known as congenital dysplasia of the hip; examples of the third group are anomalies of the lumbosacral portion of the vertebral column, resulting from man's change from the quadruped to the biped gait. Many developmental changes in the spinal column have taken place and certain anomalies are occasionally seen.

All congenital deformities cannot be classified into these groups in the light of present knowledge although many of them no doubt may be so classified as that knowledge improves. Prevention of congenital deformities may seem impossible although the results of work done in the last few years on the influence of certain deficiency diets in pregnant animals seem to indicate that some of the embryologic maldevelopments may be influenced by nutrition.

Developmental anomalies are likewise a source of troubling and disabling deformities. Among these may be mentioned certain disturbances of growth in the epiphyses of children which are known as epiphyseal osteochondrosis. Such conditions lead to deformities of the surfaces of the joints and later in life cause painful joints. Severe infections of joints due to pyogenic (pus-forming) organisms formerly were a frequent cause of severe damage which often led to deformities and disabilities, but with the development of chemotherapy (sulfonamide drugs, penicillin and streptomycin) these infections were greatly reduced if not prevented. Anterior poliomyelitis is another outstanding cause of disabilities and deformities of adolescence and adult life.

Deformities with their attending disabilities may follow injuries of the bones, joints, muscles and tendons or skin. Any one of these structures, if severely injured and not adequately repaired, will become a potential source of deformity and disability. A fracture that is allowed to heal with fragments of bone in an improper position may cause the patient to walk with the extremity out of proper alignment and in time may lead to serious disability of the neighbouring joint. In the same way, a fracture of the bones in the region of the ankle not accurately reduced, in time, because of abnormal wear and tear on the joint surfaces, may lead to traumatic arthritis and severe disability. Injuries of muscles and tendons not adequately cared for may produce an unbalanced function of an extremity or part and lead to deformity and disability. In a like manner, scars from severe burns often cause contractures or shortening of the soft tissues on one side of a joint and lead to severe deformities and marked disability. In all these instances, the best prevention is early and adequate treatment designed to produce the best possible function with the least possible deformity. Thus, it may be seen that orthopaedic surgery must always be regarded as a preventive form of medical or surgical treatment as well as a curative and reconstructive form of treatment.

Methods and Procedures.—From a specialty which originally depended on the use of heavy braces, splints and methods of treatment which produced rest has evolved an active surgical specialty which is concerned with the correction of existing faults and prevention of the later development of deformities and disabilities by surgical procedures. With the availability of newer adjuncts to surgical treatment, such as chemotherapy, blood substitutes and improved methods of anaesthesia, early restoration of badly shattered parts can be accomplished. The achievements of orthopaedic surgery in World War II are ample evidence of this fact. Wounds were surgically cleaned, transfusions were given and chemotherapy was started so that after a few days the wound could be closed if necessary by a skin graft and the patient returned to a general hospital where his fracture could heal under nearly ideal circumstances. Much time was saved, a great deal of suffering was eliminated and early restoration of function was brought about.

Orthopaedic surgeons have for a considerable time recognized the importance of reconstructive surgery of the spinal column and extremities. Fractures which have failed to unite or have united in a faulty position are constantly being treated by operation. Bone grafts are being used every day and many types of bone grafting have been developed to adapt this useful technique to a wide variety of purposes.

Tendons are being repaired by tendon grafting and by tendon transplantation if indicated. It is possible, for instance, in the case of hopeless destruction of the musculospiral nerve in the arm, to restore the function of the hand almost to normal by the transplantation of two or three tendons. The common use of skin-grafting procedures to replace extensive scars has greatly advanced reconstructive surgery. The various types of skin-grafting procedures are also used to repair extensive chronic ulcers which are painful and disabling.

Surgical methods have been developed to equalize the length of a lower extremity in cases in which a marked difference in length of the extremities impairs the patient's usefulness or threatens to cause further disability. This may be accomplished by lengthening the shorter leg, by shortening the longer leg or by retarding growth in the longer leg.

The development of better metals for use in the internal fixation and repair of fractures has occupied the attention of many orthopaedic surgeons. There were available at mid-20th century much stronger metals that produced much less reaction in the tissues than the metals that were used previously. With the improved materials has grown a better understanding of how to use these devices and better tools for their handling have been invented.

Many diseases of the skeleton are being studied and their relationship to other organs of the body gradually revealed. Deficiency states and bony diseases secondary to tumours of the parathyroid glands and to other glands of internal secretion are gradually becoming better understood, and better means of treating them are being found. The importance of prevention of deformities caused by various types of arthritis is well known and the more crippling deformities are much less frequently seen

than they were in the past.

The knowledge of malignant tumours of bone and of tumours of muscles and tendons is slowly improving. Early recognition of these conditions and the prompt use of surgical procedures or X-ray treatment have made many patients more comfortable and in many instances have saved lives.

Improvement in our knowledge of methods of amputation when such procedures become necessary and improvement in the types of artificial limbs have greatly reduced the disabling effects of these procedures. Improvements in kineplasty (plastic amputation) made this procedure practicable. By this means, tendons and muscles in amputation stumps can be used to move artificial hands.

The recognition of the fact that long periods of rest in bed, which were once strongly advocated by orthopaedic surgeons, are in many instances deleterious has shortened the period of hospitalization for many patients and has greatly reduced the long periods of convalescence which frequently were thought necessary in the treatment of diseases and injuries of the spinal column and extremities.

Methods of diagnosis and treatment are constantly changing. New ideas are presented, tried and cast off or developed. As the specialist develops he finds himself more and more confronted with new things to learn. As specialties develop and each field grows larger, the individual specialists find themselves more and more dependent on other specialists for collaboration in the care of complicated problems in medicine. In this respect the orthopaedic surgeon is in the same position as specialists in other branches.

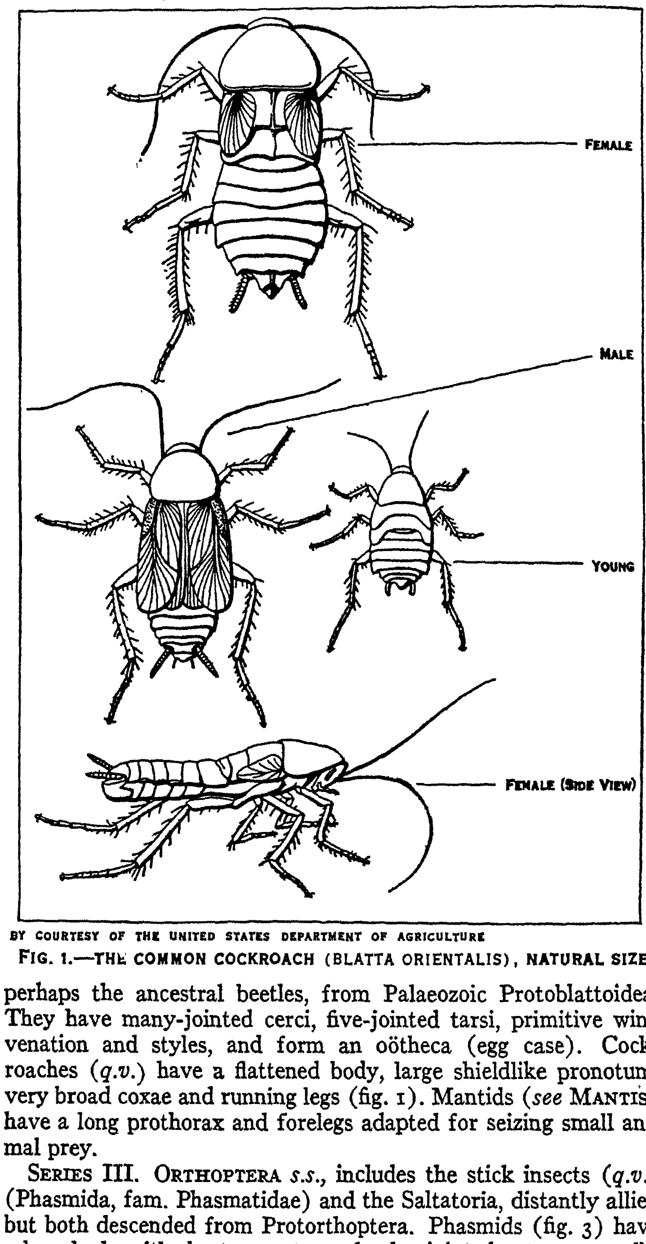
ORTHOPTERA, the zoological name of that order of insects which, in conventional classification, includes the cockroaches, mantids, stick insects, grasshoppers, locusts, katydids, crickets and their allies. The earwigs, also long included, are placed in a separate order, the Dermaptera (*see* EARWIG). Essentially terrestrial, many Orthoptera run rapidly or jump vigorously, but few are strong fliers, and wings are often reduced or absent. Most are relatively large, and some are giants among insects. Many possess sound-producing organs and stridulate loudly, while others make crackling noises in flight. The wings are net-veined, the fore wings being narrower than the hind and more or less hardened to form tegmina; the membranous hind wings have a large posterior lobe that folds fanwise in repose. The mouth parts are of biting type with a four-lobed ligula, and most often the antennae are long and threadlike and ocelli are present. The prothorax is large and movable, the mesothorax and metathorax are more or less fused and a pair of cerci terminates the abdomen. Metamorphosis is incomplete. About 16,000 species are known; the United States has about 1,300 species and subspecies, Europe about 550 and Britain 31 (exclusive of naturalized alien species).

As usually defined, the Orthoptera is an order of convenience, for it includes only part of the orthopteroid insects and comprises five groups equal in rank to others customarily treated as orders. Thus, termites (order Isoptera) are closer to cockroaches than the latter are to grasshoppers. Many classifications of orthopteroid insects were proposed from 1908 to 1940, but none became standard. The classification here used is derived from those of L. Chopard, F. E. Zeuner and Kjell Ander (1938–39). For convenience all groups except the Saltatoria are often lumped as Cursoria.

SERIES I. GRYLLOBLATTARIA, contains one order (Grylloblattoidea), one family (Grylloblattidae), two genera and five species found in Japan and western North America. Wingless, thysanuriform, with five-jointed tarsi, long many-jointed cerci, long ovipositor and styles, these most primitive of living Orthoptera seem to be only slightly modified survivors of the ancient Protorthoptera and resemble the ancestors of the other two series.

SERIES II. DICTYOPTERA (OÖTHECARIA), includes the cockroaches (Blattoidea, fam. Blattidae) and mantids (Mantoidea, fam. Mantidae), both descended, together with the termites and

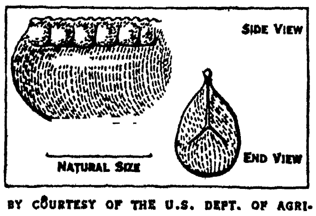


BY COURTESY OF THE UNITED STATES DEPARTMENT OF AGRICULTURE

FIG. 1.—THE COMMON COCKROACH (BLATTA ORIENTALIS), NATURAL SIZE

perhaps the ancestral beetles, from Palaeozoic Protoblattoidea. They have many-jointed cerci, five-jointed tarsi, primitive wing venation and styles, and form an oötheca (egg case). Cockroaches (*q.v.*) have a flattened body, large shieldlike pronotum, very broad coxae and running legs (fig. 1). Mantids (*see* MANTIS) have a long prothorax and forelegs adapted for seizing small animal prey.

SERIES III. ORTHOPTERA *s.s.*, includes the stick insects (*q.v.*) (Phasmida, fam. Phasmatidae) and the Saltatoria, distantly allied but both descended from Protorthoptera. Phasmids (fig. 3) have a long body with short pronotum, slender jointed antennae, walking legs, five-jointed tarsi and short ovipositor. Wings are often absent; tegmina are very short except in the leaf insects (*q.v.*).



BY COURTESY OF THE U.S. DEPT. OF AGRICULTURE

FIG. 2.—EGG CAPSULE (OÖTHECA) OF AMERICAN COCKROACH (PERIPLANETA AMERICANA)

The Jumping Orthoptera (Saltatoria) are the dominant order of orthopteroid insects, and include the familiar grasshoppers, locusts, katydids and crickets. They have hind legs adapted for leaping, tarsi less than five-jointed, a well-developed ovipositor and often stridulatory organs in the male.

Those of the first suborder, ENSIFERA, have long threadlike antennae, three- or four-jointed tarsi, a long ovipositor, auditory organs on the fore tibiae and male tegmina often formed for stridulation. Of the three chief families, the Gryllacrididae include cricket locusts and cave crickets. The Tettigoniidae are long-horned grasshoppers (*see* GRASSHOPPER) and katydids (*q.v.*), with four-jointed tarsi and a long broad ovipositor. The Gryllidae

are crickets (*q.v.*), with three-jointed tarsi and a slender ovipositor; their tegmina lie flat on the back and bend abruptly down at the sides (fig. 4).

The second suborder, CAELIFERA, has short, jointed antennae and tarsi with three or fewer joints. The Tridactylidae resemble mole crickets but are closer to locusts in structure. The Acrididae are the short-horned grasshoppers (*see* GRASSHOPPER) and true locusts (*q.v.*), with narrow horny tegmina, short ovipositor, short unjointed cerci and auditory organs on the base of the abdomen. Many stridulate by scraping a toothed ridge on the hind femur against a sharp-edged vein on the closed tegmen; some make buzzing or crackling noises in flight.

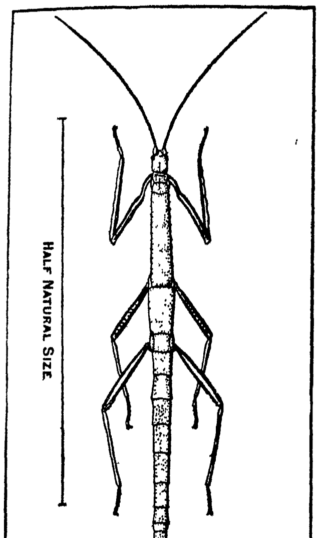


FIG. 3.—STICK INSECT (CARAUSIUS MOROSUS)

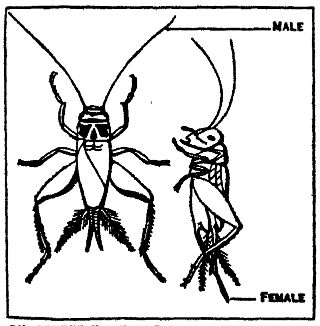
Natural History.—Eggs of Orthoptera are cylindrical to oval; the oöthecae of blattids (fig. 2) and mantids contain ten or more eggs. Spermatophore fertilization is the rule, and parthenogenesis is common, notably in phasmids. Newly hatched nymphs are wingless, the wing pads developing as growth proceeds. Many Saltatoria are notorious stridulators, especially the katydids and crickets, some of which can be heard a mile away. Apterism, or lack of wings, is common (fig. 3), and among Saltatoria wings are often reduced to the sound-producing portions of the tegmina only. Most Orthoptera are herbivorous, some being serious crop pests. Many cockroaches and crickets are omnivorous, and the domestic species injure a great variety of materials; mantids are predacious upon insects.

Each major family of Saltatoria has tree-, shrub-, herb- and ground-dwelling species, though Tettigoniidae are more arboreal than Acrididae or Gryllidae. Many Gryllacrididae and Gryllidae, notably the mole crickets, are subterranean, while the small wingless cricket *Myrmecophila* lives in ant nests. The cricket *Hydropedeticus,* one of the very few aquatic Orthoptera, skates actively over streams in Fiji much as do the Gerridae.



BY COURTESY OF THE U.S. DEPT OF AGRICULTURE

FIG. 4.—HOUSE CRICKET (GRYLLULUS DOMESTICUS)

The largest families are worldwide in range, though all diminish rapidly in species as the cooler zones are approached, and very few mantids or phasmids occur outside the tropics. Some house pests, such as the oriental cockroach (*Blatta orientalis*), have become cosmopolitan. Primitive cockroaches (Protoblattoidea) are among the oldest known insects, exceeding all other insect fossils in some Upper Carboniferous strata.

After the Permian period cockroaches lost their pre-eminence, and gradually declined to their present insignificant status among insects.

ORTIGUEIRA, a seaport of northwestern Spain, in the province of Corunna; on the northern slope of the Sierra de la Faladoira, on the river Nera and on the eastern shore of the Ría de Santa Marta—a winding, rock-bound and much indented inlet of the Bay of Biscay, between Capes Ortegal and Vares. Pop. (1940) 1,479 (mun., 22,152). The population is scattered. The industries are fishing and farming. There is an important coasting trade, despite the dangerous coastline and the fogs and gales.

ORTLER, the highest point (12,802 ft.) in Tirol, and in the whole of the Eastern Alps. It is a great snow-clad mass, which rises east of the Stelvio pass, and a little south of the upper valley

ORTLER ALP FARM, ON THE SLOPES OF THE HIGHEST PEAK (12,802 FT.) IN THE EASTERN ALPS, BETWEEN THE VALLEYS OF TRAFOI AND SULDEN

of the Adige between the valleys of Trafoi (northwest) and of Sulden (northeast). It was long considered inaccessible, but was conquered in 1804 by three Tirolese peasants. The first traveller to make the climb was Herr Gebhard in 1805 (sixth ascent). Many routes to the summit are now known.

ORTNIT or **OTNIT,** German hero of romance, was originally Hertnit or Hartnit, the elder of two brothers known as the Hartungs, who correspond in German mythology to the Dioscuri. His seat was at Holmgard (Novgorod), according to the *Thidrekssaga* (chapter 45), and he was related to the Russian saga heroes. Later on his city of Holmgard became Garda, and in ordinary German legend he ruled in Lombardy. Hartnit won his bride, a Valkyrie, by hard fighting against the giant Isungs, but was killed in a later fight by a dragon. His younger brother, Hardheri (replaced in later German legend by Wolfdietrich), avenged Ortnit by killing the dragon, and then married his brother's widow. Ortnit's wooing was corrupted by the popular interest in the crusades to an Oriental *Brautfahrtsaga,* bearing a resemblance to the French romance of Huon of Bordeaux (*q.v.*).

See editions of the *Heldenbuch* and one of *Ortnit* and *Wolfdietrich* by Dr. J. L. Edlen von Lindhausen (Tuebingen, 1906).

ORTOLAN, *Emberiza hortulana,* a bunting (*q.v.*) celebrated for the delicate flavour of its flesh. A native of most European countries—the British Islands excepted—as well as of western Asia, it migrates southwards in autumn and returns about the end of April. Its distribution throughout its breeding range seems to

be very local. In habits it much resembles the yellowhammer, but it wants the bright colouring of that species. The monotonous song of the cock is also much of the same kind. The nest is placed on or near the ground, but the eggs seldom show the hair-like markings which characterize those of most buntings. Its natural food consists of beetles, other insects and seeds. Ortolans are netted in great numbers, kept alive in a darkened room and fed with oats and millet. In a very short time they become enormously fat and are then killed for the table.

ORTONA A MARE, seaport and episcopal see, Abruzzi, Italy, province of Chieti, 12 mi. directly E. of that town, 105 mi. by rail S.S.E. of Ancona. Pop. (1936) 9,215 (town); 20,210 (commune). It is on a promontory 230 ft. above sea level, and connected with the port below by a funicular railway. The ruined castle has magnificent views. The cathedral (1127) has a fine portal by a local artist, Nicolo Mancini (1311). The town occupies the site of the ancient Ortona, a seaport of the Frentani.

ORURO, a department and town of Bolivia. The department is bounded north by La Paz, east by Cochabamba and Potosí, south by Potosí and west by Chile; it occupies part of an ancient lacustrine basin lying between the eastern and western ranges of the Andes, and has an area of 20,386 sq.mi., the greater part of which is semiarid and covered with extensive saline deposits. The Desaguadero river, the outlet of Lake Titicaca, flows southward into Lake Pampa-Aullagas, or Poopó, on the eastern side of the department near the Cordillera de los Frailes. Lake Poopó is 12,106 ft. above sea level, or 400 ft. lower than Titicaca, and its waters discharge through a small outlet, called the Lacahahuira, into the lagoon and saline morasses of Coipasa (12,073 ft. elevation) in the southwest corner of the department. Oruro is almost exclusively a mining department, the country being too arid and too cold for agriculture. With the exception of a narrow strip along the foothills of the Cordillera de los Frailes, where a few cattle, mules, llamas and sheep are reared, little of the area is suitable even for grazing. In the vicinity of the capital, in the northeast part of the department, there are large deposits of tin, silver, tungsten and copper; Oruro is the second largest producer of tin in the republic. Population (1947 est.), 203,500.

The capital of the department is Oruro, 125 mi. S.S.E. (direct) of La Paz; it is an old mining town dating from the 17th century, when it is said to have had a population of 70,000. The estimate of 1946 gave it a population of 50,000, the greater part of whom are Indians and mestizos. A considerable number of foreigners are interested in the neighbouring mines. The elevation of Oruro is 12,158 ft. above sea level, and its climate is characterized by a cool summer with light rainfall and a cooler but sunny winter, with nightly frosts and an occasional snowstorm. The mean temperature of the warmest month, December, is 51° F. and that of the coolest month, June, is 31° F. There is a much greater difference than this between day and night temperatures, both in summer and winter. Oruro is connected by rail with La Paz and Cochabamba, with Antofagasta, 578 mi. away, and with Arica (via Viacha), 380 mi. distant. (G. M. McB.)

ORVIETO (anc. *Volsinii* [*q.v.*], later *Urbs Vetus*, whence the modern name), town and episcopal see, province of Terni, Italy, on the Paglia, a tributary of the Tiber, 78 mi. by rail N. by W. of Rome. Pop. (1936) 8,883 (town); 21,469 (commune). It crowns an isolated rock, 1,033 ft. above sea level, 640 ft. above the plain, commanding splendid views, and is approached by a funicular railway. The town has a large number of fine 13th-century houses and palaces. The splendid cathedral dedicated to the Virgin was begun at least as soon as 1288 on the site of two older churches erected to commemorate the miracle of Bolsena (*q.v.*), and was decorated by many mediaeval painters and sculptors. The exterior is black and white marble; the interior is gray limestone with bands of dark basaltic stone. There is a large rectangular nave, with semicircular recesses for altars, opening out of the aisles, north and south, two transeptal chapels and a short choir. A fine polychrome monument is the west façade, of richly sculptured marble from the designs of Lorenzo Maitani of Siena, divided into three gables with intervening pinnacles; it is a reproduction of the façade of Siena cathedral. The mosaics are modern. The four wall surfaces that flank the three western doorways are decorated with beautiful sculpture in relief, executed under Maitani's direction until his death in 1330. In the interior, the Cappella del Corporale possesses a large silver shrine, resembling the cathedral façade, enriched with countless figures in relief and subjects in translucent coloured enamels—one of the most important specimens of early silversmith's work. It was begun by Ugolino Vieri of Siena in 1337, and was made to contain the Holy Corporal from Bolsena (*q.v.*). On the south side is the chapel of S. Brizio, separated from the nave by a fine 14th-century wrought-iron screen. The walls and vault are covered with fine and well preserved frescoes—among the noblest works of Fra Angelico and Luca Signorelli, painted 1499 to 1504—the latter being of especial importance in the history of art because of their great influence on Michelangelo in his early days. The choir stalls are fine and elaborate specimens of *tarsia* and rich wood carving—the work of Pietro del Minella (1430–41). In 16th-century sculpture the cathedral is especially rich, containing many statues, groups and altar reliefs by Simone Mosca and Ippolito Scalza. Close by are two Gothic buildings, the bishop's palace (1264) and the Palazzo dei Papi (1264–1302), the latter with a huge hall now containing the Museo Civico, with various mediaeval works of art, and also objects from the Etruscan necropolis of the ancient Volsinii (*q.v.*). The Palazzo Faina has another interesting Etruscan collection. The Palazzo del Comune is Romanesque (12th century). S. Andrea and S. Giovenale are also Romanesque churches of the 11th century; both contain later frescoes. To the 11th–12th century belongs the ruined abbey of SS. Severo and Martirio, 1 mi. S. of the town. The church of S. Domenico contains one of the finest works in sculpture by Arnolfo di Cambio, the tomb with recumbent effigy of the Cardinal de Braye (1282), with much beautiful sculpture and mosaic. There are a few buildings by Sammicheli of Verona, architect of the cathedral from 1509 to 1528. The fortress built in 1364 by Cardinal Albornoz has been converted into a public garden. The well, now disused, called Il pozzo di S. Patrizio, is one of the chief curiosities of Orvieto. It is 200 ft. deep to the water level and 42 ft. in diameter, cut in the rock, with a double winding inclined plane, so that asses could ascend and descend to carry the water from the bottom. It was begun by the architect Antonio da San Gallo the younger in 1527 for Clement VII and was finished by Simone Mosca under Paul III. (*See* UMBRIA.)

See L. Fumi, *Il Duomo d' Orvieto e i suoi restauri* (1891), *Orvieto, note storiche e biografiche* (1891), and other works; P. Perali, *Orvieto* (1919). (T. A.)

ORYX, the scientific name of a group of African antelopes of large size with long horns, which are present in both sexes, and long tufted tails. They are desert animals. The true oryx is the east and northeast African beisa oryx (*Oryx beisa*), which is replaced in South Africa by the gemsbok (*q.v.*). In northern Africa the group is represented by *O. algazel,* and in Arabia by *O. leucoryx*. (*See* ANTELOPE.)

ORZESZKOWA (*née* Pawlowska), **ELIZA** (1842–1910), Polish novelist, born near Grodno, of the noble family of Pawlowski. In her 16th year she married Piotr Orzeszko, a Polish nobleman, who was exiled to Siberia after the insurrection of 1863. She wrote a series of powerful novels and sketches, dealing with the social conditions of her country. *Eli Makower* (1875) describes the relations between the Jews and the Polish nobility, and *Meir Ezofowicz* (1878) the conflict between Jewish orthodoxy and modern liberalism. *On the Niemen* (1888), perhaps her best work, deals with the Polish aristocracy, and *Lost Souls* (1886) and *Cham* (1888) are on rural life in White Russia. She died at Grodno on May 18, 1910.

OSAGE, a tribe of American Indians formerly on the Osage and Arkansas rivers in Missouri and Arkansas. Their speech is Siouan; their culture that of the plains. The original population is estimated at 5,000; in 1921 there were 2,200 in Oklahoma. Oil royalties, land leases and interest on trust funds held for them by the government make them one of the richest populations in the world.

See F. La Flesche, *Bur. Am. Ethn. Rep.*, xxxvi (1921); xxxix (1925).

OSAGE ORANGE (*Maclura pomifera*), a thorny tree with large, yellow, somewhat orangelike fruit. The tree, which is the only species of its genus, belongs to the mulberry family (Moraceae). It is native to rich soils in the south-central United States from Missouri and Kansas to Texas, but has been planted extensively in the Mississippi valley and occasionally in the eastern states, being hardy in New England. The very hard, strong, flexible, yellow wood, formerly used for bows and war clubs by the Osage and other Indians west of the Mississippi, is utilized for railway ties and fence posts. Osage orange is also known as bowwood and as *bois d'arc*. The wood yields a yellow dye principle.

OSAKA, the chief industrial city of Japan (*q.v.*). Pop. (1950) 1,956,136. It lies in a plain bounded, except westward, where it opens on Osaka bay, by hills of considerable height, on both sides of the Yodogawa, or rather its headwater the Aji (the outlet of Lake Biwa), and is so intersected by river branches and canals as to suggest a comparison with a Dutch town. Steamers ply between Osaka and Kobe-Hiogo or Kobe, and Osaka is an important railway centre. The opening of the railway (1873) drew foreign trade to Kobe, but a harbour for ocean steamers was constructed at Osaka. Shin-sai Bashi Suji, the principal thoroughfare, leads from Kitahama, the district lying on the south side of the Tosabori, to the iron suspension bridge (Shin-sai Bashi) over the Dotombori. The former foreign settlement is at Kawaguchi at the junction of the Shirinashi and the Aji. It is the seat of a number of European mission stations. Buddhist and Shinto temples are numerous. The principal secular buildings are the castle, the mint and the arsenal. The castle was founded in 1583 by Hideyoshi; the enclosed palace, probably the finest building in Japan, survived the capture of the castle by Iyeyasu (1615), and in 1867 and 1868 witnessed the reception of the foreign legations by the Tokugawa shoguns; but in the latter year it was fired by the Tokugawa party. It later provided military headquarters, containing a garrison and an arsenal. The whole castle is protected by high and massive walls and broad moats. The mint, erected and organized by Europeans, was opened in 1871. Osaka possesses ironworks, sugar refineries, cotton-spinning mills, shipyards and a great variety of other manufactures.

Osaka owes its origin to Rennio Shonin, eighth head of the Shin-Shu sect, who in 1495–96 built, on the site now occupied by the castle, a temple which became the principal residence of his successors. In 1580, after ten years' successful defense of his position, Kenryo, the 11th "abbot," was obliged to surrender; and in 1583 the victorious Hideyoshi made Osaka his capital. The city brought several suburban districts within its boundaries in 1925, becoming temporarily the most populous city in Japan. In 1909 one-third of the city was destroyed by fire; though it was rebuilt with wider streets and better buildings, its factories and warehouses compared less favourably with European and U.S. standards than those of Tokyo until after World War I, when a program of city planning was carried a long way. Thousands of buildings were destroyed during World War II, but by 1949, 100,000 new houses had been constructed, and more than 9,000 factories had resumed operations. Osaka boasts of its advanced municipal government. Trade grew rapidly before World War II, and a number of foreign-going ships load and unload in Osaka harbour, which is being continuously extended and improved. The city was enlarged in 1926, by the absorption of outlying districts, to form Greater Osaka. Osaka, like Tokyo and Kyoto, as well as being a municipal administrative unit is an urban prefecture (*fu*).

OSAWATOMIE, a city of Miami county, Kan., U.S., 4⅝ mi. S. by W. of Kansas City, on the Missouri Pacific railroad. Pop. (1950) 4,347. It is near oil and gas fields, in a farming and grazing region, and has railroad shops. A state hospital for the insane is 1 mi. N.E. Osawatomie was settled about 1854 by colonists sent out by the Emigrant Aid company. The name was derived from Osage and Potawatomi. It was the scene of many clashes between the proslavery and the free-soil factions of Kansas and Missouri, notably on Aug. 30, 1856, when Capt. John Brown (who had come to Osawatomie in 1855) and 40 followers attempted to repulse an attack by Gen. John W. Reid, at the head of 400 Missourians. They were quickly overpowered and the town was looted and practically destroyed.

OSBORN, HENRY FAIRFIELD (1857–1935), palaeontologist, was born at Fairfield, Conn., Aug. 8, 1857. He graduated from Princeton university (1877) and continued his studies under F. M. Balfour and Thomas Huxley. His professorships included natural history and anatomy at Princeton (1881–91); biology and zoology until 1910, and the deanship of the faculty of pure science (1892–95) at Columbia university. From 1910 to 1935 he held the research professorship in zoology at Columbia university. His connection with the American Museum of Natural History began as curator of the department of vertebrate palaeontology (1891–1910), and was followed by a number of offices till 1908, when he became president. After 1900 he was connected with the United States geological survey, first as vertebrate palaeontologist and after 1924 as senior geologist. Among offices too numerous to mention, he had important connections with the Canadian geological survey, the New York Zoological society and the Carnegie institute. He declined the proffered secretaryship of the Smithsonian institution.

The American Museum of Natural History extension school service, its unique exhibition halls and the organization of a complete survey of the geological succession of the higher vertebrates of North America were the result of Osborn's efforts. His extensive researches chiefly concerned the palaeontology of the vertebrates. His publications dealt with almost all groups of animals and reptiles, but made especially important contributions to the knowledge of the rhinoceroses, horses, titanotheres and dinosaurs. He founded a flourishing school of vertebrate palaeontology which included the names of numerous brilliant younger men of science. He did much toward the determination of relative ages of extinct mammals in North America, and performed important services in working out a correlation between the Tertiary and mammal horizons of Europe and America. He also studied and wrote on the philosophical bearings of his work. He was called, by the Royal society of London at the time of his election to membership, "one of the most distinguished palaeontologists of our time."

His scientific writings (1877–1928) in geology, palaeontology, anthropology and biology comprise 755 titles, including memoirs on extinct reptiles and mammals. Osborn died Nov. 6, 1935.

His books combine literary art and scientific information. Among the most important are: *From the Greeks to Darwin* (1894); *Evolution of Mammalian Molar Teeth* (1907); *The Age of Mammals* (1910); *Huxley and Education* (1910); *Men of the Old Stone Age* (1915); *Origin and Evolution of Life* (1917); *The Earth Speaks to Bryan* (1925); *Evolution and Religion in Education* (1926); *Creative Education* and *Man Rises to Parnassus* (1927).

See "Eminent Living Geologists," *Geological Magazine*, vol. 4, pp. 193–196, new series, decade 6 (London, 1917).

OSBORNE, a former royal residence in the Isle of Wight, Eng., southeast of East Cowes. The name of the manor in early times is quoted as Austerborne or Oysterborne. In 1845 it was purchased by Queen Victoria, who died there in 1901. King Edward VII presented the property to the nation. A part of the house was transformed into a convalescent home for officers of the navy and army, opened in 1904.

In 1903 there was opened on the Osborne estate a Royal Naval college, which in 1921 was closed down; the cadets thenceforward joined Dartmouth college.

OSCAN was the name given by the Romans to that dialect (*lingua Osca*) which they found spoken by the Osci of Campania. But inscriptional and other records (*i.e.*, local and personal names and glosses in ancient authors) manifestly of the same dialect have been found not only in Campania, where the dialect was, according to the most probable interpretation of the evidence, not original, but seems to have been imposed upon the Oscans by Samnite invaders in the 5th century B.C., but also further south, namely in northern Apulia, Lucania, in the country of the Brutii (the "toe" of Italy), and even in the northeast angle of Sicily at Messana (the modern Messina), which was captured by the

Campanian Mamertines *c.* 289 B.C.; in Samnium proper, including the territory of the Frentani and Hirpini; and finally, further north, in the country of the Paeligni, Marrucini and Vestini. Thus there are distinguished, geographically, and dialectally, three main groups of Oscan: (1) Central Oscan of Campania and the Samnite tribes, (2) Southern Oscan, and (3) Northern Oscan. These are all closely related to one another as compared with the dialect of the Volsci and of the Umbrian townships (Iguvium, the modern Gubbio; Tuder, modern Todi; and one or two others); while Oscan, Volscian and Umbrian, taken together, make one of the two great divisions—the other being Latin (*q.v.*) with Faliscan—into which the Italic branch of the Indo-European family of languages falls. Since the Samnitic tribes, whose expansion by successive migrations—"sacred springs" as they were called—diffused the Oscan speakers from their home in central Italy, knew their land (in Latin, Samnium) by the name *Safinim*, it has been proposed to describe their dialects as "Safine," a title at once more comprehensive and historically truer than "Oscan." The stock to which the Samnites belonged used commonly a suffix *-no-* (*e.g.*, in *Sabi-ni*) to form their tribal names, as distinguished from the suffixes *-co-* and *-(a)ti-* of an earlier stratum of population (*e.g.*, in *Vols-ci, Tea-te*). In names like *Marru-ci-ni, Ardea-ti-ni*, the superimposed *-no-* suffix bears witness to a conquest or overlordship of the earlier by the later stock.

Until the Roman advance gradually replaced it by Latin—important stages of this advance are marked not so much by the three Samnite wars as by the destruction of Capua in 211 B.C. and the Social War of 91–89 B.C.—Oscan held its place as a language in recognized official and educated usage side by side with, or instead of, Latin or Greek. The poet Ennius is said to have spoken all three tongues (Gellius 17,17,1), and if Strabo (5, p.233 C) may be trusted, the rude farces or puppet-shows introduced from the Oscan town Atella (*fabulae Atellanae, ludi Osci*) were actually performed at Rome in Oscan. The latest Oscan inscriptions, scratched on the walls of houses at Pompeii, were written shortly before the eruption of Vesuvius which overwhelmed that city in A.D. 79, and it is probable that the dialect, which has left its mark on modern south Italian dialects, survived in remote country districts as a local patois for some time longer. None of the Oscan inscriptions, on the other hand, is older than the 5th century B.C.

Many of the inscriptions are carefully, indeed almost with phonetic accuracy, written in a native alphabet which was itself derived, with certain necessary modifications, from the Etruscan alphabet; but a few belonging to the southern group, and including all those from Sicily, are in the Greek, and some from Lucania and elsewhere in the rustic or Colonial Latin alphabets. Over 250 in number, the majority are quite short; nevertheless, they furnish materials adequate to give us a fairly complete conspectus of the dialect. About two-thirds of the whole come from Campania, and most of those from Capua and Pompeii.

In character they fall mostly into the following classes: (1) official documents—municipal regulations (Bantia), a treaty (Nola and Abella), inscriptions relating to public works (Pompeii and elsewhere); (2) religious—an inventory of statues and altars in a sacred grove at Agnone (Samnium), the interesting group of heraldic *iovilae* (*q.v.*) from Capua, recording or prescribing special ceremonies connected with family cults, numerous simple votive and dedicatory inscriptions; (3) military and election announcements (from Pompeii); (4) private documents—epitaphs, bricks inscribed with names, and (from Campania) a few belonging to the interesting group of curses, inscribed on lead and deposited in tombs; (5) coin legends, including those of the Social War reading *vìtelliú, i.e.*, "Italia."

Oscan has many peculiarities which distinguish it from Latin in sound changes, word forms and vocabulary; in syntax the differences are much less marked. But it also possesses certain features which distinguish it amongst the Italic dialects themselves. Their nature and extent may be indicated roughly by a specimen text (on a sundial found at Pompeii):

> mr atiniís mr kvaisstur eítiuvad
> múltasíkad kúmbennieís tangi(nud)
> aamanaffed

This in Latin would be:

> M(a)r(a) Atinius M(a)r(ae) (filius) quaestor pecunia
> multaticia conventus scitu
> fieri iussit

(Mara Atinius, son of Mara, quaestor, in accordance with a decree of the assembly, had this set up from fine-money.)

Buck, *Grammar of Oscan and Umbrian* (1904), all three with bibl. New inscriptions are reported in the official *Notizie degli Scavi* (Hoepli), but often more promptly in F. Ribezzo's *Rivista Indo-greco-italica* (since 1917); those discovered between 1897 and 1925 will be found collected by W. Schwering and M. Bacherler in Bursian's *Jahresbericht*, vol. 176 (1916–18), pp. 69 *sqq.*, Bacherler, *ibid.* vol. 184 (1920), pp. 140 *sqq.*, vol. 205 (1925), pp. 51 *sqq.; see* also Ribezzo, *l.c.*, vol. 8 (1924), pp. 83 *sqq.; résumés* of discoveries and new studies in the field appear regularly also in *Glotta* (since 1907) and in the *Indogermanisches Jahrbuch* (since 1912). G. Herbig, in M. Ebert's *Real-lexikon der Vorgeschichte, s.v.* Italiker (1925; bibl.), and R. S. Conway in *Cambridge Ancient History*, vol. iv. (1926) pp. 444 *sqq.*, give summary accounts of the Italic peoples and dialects. (J. WH.)

OSCAR I. (1799–1859), king of Sweden and Norway, was the son of General Bernadotte, afterwards King Charles XIV. In 1838 the king began to suspect his heir of plotting with the Liberal party to effect a change of ministry, or even his own abdication. Oscar, however, avoided an actual rupture. After his accession (March 8th, 1844) it appeared that his liberalism was very restricted. He refused any radical reform of the cumbrous and obsolete constitution. But one of his earliest measures was to establish freedom of the press. Most of the legislation during his reign aimed at improving Sweden's economic position.

In foreign affairs Oscar I. was a friend of the principle of nationality. In 1848 he supported Denmark against Germany; placed Swedish and Norwegian troops in cantonments in Fünen and North Schleswig (1849–1850); and mediated the truce of Malmö (August 26, 1848). He was also one of the guarantors of the integrity of Denmark (London protocol, May 8, 1852). Oscar I. left four sons, of whom two, Carl (Charles XV.) and Oskar Fredrik (Oscar II.), succeeded to his throne.

See T. Almén, *Ätten Bernadotte* (Stockholm, 1896); and C. E. Akrell, *Minnen från Carls XIV., Oscars I. och Carls XV. Lagar* (Stockholm, 1884, 1885). Also NORWAY: *History*, and SWEDEN: *History*.

OSCAR II. (1829–1907), king of Sweden and Norway, son of Oscar I., was born at Stockholm on Jan. 21, 1829. In 1857 he married Princess Sophia Wilhelmina, youngest daughter of Duke William of Nassau. He succeeded his brother Charles XV. on Sept. 18, 1872, and was crowned in the Norwegian cathedral of Drontheim on July 18, 1873. At his accession he adopted as his motto *Brödrafolkens Väl*, "the welfare of the brother folk," and from the first he realized the essential difficulties in the maintenance of the union between Sweden and Norway. The political events which led up to the final crisis in 1905, by which the thrones were separated, are dealt with in the historical articles under NORWAY and SWEDEN. But it may be said that the peaceful solution eventually adopted could hardly have been attained but for the tact and patience of the king himself. He declined, indeed, to permit any prince of his house to become king of Norway, but better relations between the two countries were restored before his death, which took place at Stockholm on Dec. 8, 1907. His acute intelligence and his aloofness from the dynastic considerations affecting most European sovereigns gave the king considerable weight as an arbitrator in international questions. At the request of Great Britain, Germany and the United States in 1889 he appointed the chief justice of Samoa, and he was again called in to arbitrate in Samoan affairs in 1899. In 1897 he was empowered to appoint a fifth arbitrator if necessary in the Venezuelan dispute, and he was called in to act as umpire in the Anglo-American arbitration treaty that was quashed by the senate.

Himself a distinguished writer and musical amateur, King Oscar was a generous friend of learning and of education. His works, which included his speeches, translations of Herder's *Cid* and Goethe's *Torquato Tasso*, a play, *Castle Cronberg*, poems and historical works, were collected in 1875–76 (new and enl. ed.,

1885–88). His *Memoirs of Charles XII.* were translated into English in 1879.

See E. Lindorm, *Oscar II, och hans tid* (Stockholm, 1936).

OSCEOLA (*c.* 1804–1838), a Seminole American Indian, leader in the second Seminole War, was born in Georgia, near the Chattahoochee river. His father was an Englishman named William Powell; his mother a Creek of the Red Stick or Mikasuki division. In 1808 he removed with his mother into northern Florida. When the U.S. commissioners negotiated with the Seminole chiefs the treaties of 1832–33 for the removal of the Seminoles to Arkansas, Osceola seized the opportunity to lead the opposition of the young warriors, and declared to the U.S. agent, Gen. Wiley Thompson, that any chief who prepared to remove would be killed. Late in 1835 he murdered Charley Emathla (or Emartla), a chief who was preparing to emigrate with his people, and with a few companions shot and killed Gen. Thompson.

In 1836 Generals Edmund P. Gaines (1777–1849), Winfield Scott (1786–1866) and Richard K. Call (1791–1862) waged war against them with little effect, and the year closed with General Thomas Sidney Jesup (1788–1860) in command with 8,000 troops at his disposal. General Jesup drove the enemy from the Withlacoochee country and was pursuing them southward toward the Everglades when several chiefs expressed a readiness to treat for peace. On March 6, 1837, they agreed to cease hostilities, to prepare for emigration to Arkansas, and gave hostages to bind them to their agreement. But on June 2 Osceola came to the camp at the head of about 200 Mikasuki (Miccosukees) and effected the flight of all the Indians there, about 700 including the hostages, to the Everglades. Hostilities were then resumed, but in September, after the capture of several chiefs, Osceola requested an interview. This was granted, and by command of General Jesup he was taken captive and carried to Fort Moultrie, at Charleston, S.C., where he died in January, 1838. The war continued until 1842, but after Osceola's death the Indians did little but attack the unarmed inhabitants.

See J. T. Sprague, *The Origin, Progress and Conclusion of the Florida War* (1848).

OSCHERSLEBEN, a town in the Prussian province of Saxony, on the Bode, 24 m. by rail W.S.W. of Magdeburg, and at the junction of lines to Halberstadt and Jerxheim. Pop. (1939) 17,761. Oschersleben is first mentioned in 803. Among its industrial establishments are sugar-refineries, iron-foundries, breweries, machine-shops and brick works.

OSCILLATOR. A non-rotating device used in radio apparatus for producing alternating current. The output frequency of the oscillation is determined by the characteristics of the device.

OSCILLATORY CIRCUIT, as applied to radio apparatus, is a relatively low resistance circuit containing both inductance and capacity, such that the voltage impulse will produce a current which periodically reverses in direction.

OSCILLOGRAPH, an instrument for the delineation of alternating current wave forms. In the type devised by Duddell (*Electrician* xxxix., Sept. 1897, 636) two phosphor bronze strips under tension pass, side by side, between the poles of an electromagnet. The current is led up one strip and down the other so that they move in opposite directions at right angles to their length. A small mirror bridged across the strips is thus tilted to an extent dependent on the strength of the current. The mirror reflects a spot of light on to a photographic film whose movement at right angles to that of the light spot provides the time scale. The natural period of vibration of the strips is arranged to be very small ($\frac{1}{8,000}$–$\frac{1}{10,000}$ sec.) to enable them to move in accordance with the fluctuations of the current. Other types of oscillograph have been designed by Blondel, Irwin (the *hot-wire* oscillograph) and others. The Cathode Ray Oscillograph is available for high-frequency observations. *See* also INSTRUMENTS, ELECTRICAL: *Current Measuring Instruments;* OSISO.

OSH, a town of Asiatic Russia, in the Kirghiz A.S.S.R. in 40° 35′ N., 72° 55′ E., 31 mi. S.E. of Andijan railway terminus, at an altitude of 4,030 ft. Pop. (1933) 44,800. It is on the Ak-bara river, a tributary of the Kara-Su, in a fertile cotton, grain and fruit growing valley leading to the Alai and Pamir. The famous Takht-i-Suleiman (Solomon's Throne) rock, the theme of so many Eastern legends, is near the town and is frequented by pilgrims.

O'SHAUGHNESSY, ARTHUR WILLIAM EDGAR (1844–1880), English poet, was born in London on March 14, 1844, and at seventeen became a copyist in the library of the British Museum. Later, he specialised in ichthyology. He published his *Epic of Women* in 1870, *Lays of France,* a free version of the *Lais* of Marie de France, in 1872, and *Music and Moonlight* in 1874. He died on Jan. 30, 1880, his *Songs of a Worker* appearing immediately afterwards. In Palgrave's words, he had "a haunting music all his own."

OSHAWA, a manufacturing city and port of entry of Ontario county, Ontario, Canada, on Lake Ontario and the Canadian National and Canadian Pacific railways, 30 mi. E.N.E. of Toronto. Pop. (1951) 41,359. It contains large automobile works; flour, woollen and grist mills; furniture, sheet-metal and farm implement factories; foundries, tanneries, canneries, potteries, etc.

OSHIMA, a group of three small islands belonging to Japan, lying southwards of Kiushiu, in 30° 50′ N. and 130° E. Their names, from west to east, are Kuro-shima, Iwo-shima and Take-shima. Kuro-shima rises to a height of 2,475 ft., and Iwo-shima has an active volcano 2,480 ft. high. These islands are not to be confounded with Oshima, the most northerly island of the Izu-noshichito, or with the northern group of the Luchu Islands.

OSHKOSH, a city of Wisconsin, U.S., 82 mi. N.N.W. of Milwaukee, on the west shore of Lake Winnebago, where the Fox river flows into it; the county seat of Winnebago county. It is on federal highways 41, 45 and 110, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, the Soo Line, motor coaches and motor-truck lines. Population in 1950 was 40,934 by federal census.

Oshkosh is the seat of a state teachers' college with an enrolment of 800. Lumber used to be the main industry, but products are now highly diversified. The city has an aldermanic government.

The Fox river and Lake Winnebago early became an important line of communication, under French control, on the route between the Great Lakes and the Mississippi. Trading posts were established on the site of Oshkosh in the 18th century, and a flotilla of 50–100 fur-laden barges and bateaus was not an uncommon sight on the river.

Permanent settlement there began about 1836. The north side of the river was at first called Saukeer and the south side Algoma, but in 1840 the name Oshkosh was adopted, to honour a friendly Menominee chief.

In 1874 and in 1875 the city suffered serious loss from fire. It was chartered as a city in 1853.

OSIANDER, ANDREAS (1498–1552), German reformer, was born at Gunzenhausen, near Nuremberg, on Dec. 19, 1498. His German name was Heiligmann, or, according to others, Hosemann. After studying at Leipzig, Altenburg and Ingolstadt, he was ordained priest in 1520 and appointed Hebrew tutor in the Augustinian convent at Nuremberg. Two years afterwards he was appointed preacher in the St. Lorenz Kirche, and about the same time he publicly joined the Lutheran party, taking a prominent part in the discussion which ultimately led to the adoption of the Reformation by the city. He married in 1525. He was present at the Marburg conference in 1529, at the Augsburg diet in 1530 and at the signing of the Schmalkald articles in 1537. His vehemence, coarseness and arrogance in controversy brought him many personal enemies. The introduction of the Augsburg Interim in 1548 necessitated his departure from Nuremberg; he went first to Breslau, and afterwards settled at Königsberg as professor in its new university at the call of Duke Albert of Prussia. Here in 1550 he published two disputations, the one *De lege et evangelio* and the other *De justificatione,* which aroused a controversy still unclosed at his death on Oct. 17, 1552. While he was fundamentally at one with Luther in opposing both Romanism and Calvinism, his mysticism led him to interpret justification by faith as not an imputation but an infusion of the essential righteousness or divine nature of Christ. His party was afterwards led by his son-in-law Johann Funck, but disappeared after the latter's

execution for high treason in 1566. Osiander's son Lukas (1534–1604) and grandsons Andreas (1562–1617) and Lukas (1571–1638) were well-known theologians.

Osiander, besides a number of controversial writings, published a corrected edition of the Vulgate, with notes, in 1522, and a *Harmony* of the Gospels—the first work of its kind—in 1537. The best-known work of his son Lukas was an *Epitome* of the *Magdeburg Centuries*. *See* the *Life* by W. Möller (Elberfeld, 1870).

OSIER, the common term under which are included those species, varieties and hybrids of the genus *Salix* used in the manufacture of baskets. The chief species in cultivation are: *Salix viminalis* (the common osier), *S. triandra, S. amygdalina, S. purpurea* and *S. fragilis,* which botanically are willows. The first named, with about 40 of its varieties, formerly comprised the staple basket-making material in England. It is an abundant cropper, sometimes attaining on low-lying soils a height of 13 ft. Full topped and smooth, it is by reason of its pithy nature mainly cultivated for coarse work and is generally used as brown stuff. Some harder varieties, known as stone osiers and raised on drier upland soils, are peeled and used for fine work.

S. fragilis, with about ten varieties, is almost exclusively used by market gardeners for bunching greens, turnips and other produce.

Because of the increased demand for finer work much attention has been given (*see* BASKET) to the cultivation of the more ligneous and tougher species, *S. triandra, S. purpurea* and *S. amygdalina,* with their many varieties and hybrids.

It is commonly supposed that osiers or willows will prove remunerative and flourish with little attention on any poor, wet, marshy soil. This is, however, not the case. No crop responds more readily to careful husbandry and skilful cultivation. For the successful raising of the finer sorts of willows good, well-drained, loamy upland soil is desirable, which before planting should be deeply trenched and cleared of weeds.

At any time, from late winter to early spring, the ground may be planted with "sets" (*i.e.,* cuttings) of about 9 to 16 in. in length, taken from clean, well-ripened rods. These are firmly set to within 3 to 6 in. of the top in rows, 16 to 20 in. apart and spaced at intervals of 8 to 12 in. Yearling sets are largely planted, but the practice of the best Midland and west of England growers proves the superior productiveness of sets cut from two yearling rods. Great care should be exercised in planting lest the bark be fractured, loosened or removed from the wood, and if not subject to periodical alluvial floods the ground should be manured yearly. The coarser *S. viminalis* may be raised on lowland soil if not waterlogged or marshy. The more valuable kinds are known as: new kind, black mauls, Spaniards, glibskins, long-bud, long-skin, Lancashire red-bud, French, Italians, Pomeranians and councillors and scores of other local names. A hybrid of *S. viminalis* and *S. triandra,* known as black-top, has been found to produce the heaviest crops on the best Leicestershire grounds.

Cutting and binding take place in early winter after the fall of the leaf, the crop being known as green whole stuff. The coarser kinds are sorted, cured (dried in the sun and wind) and stacked ready for market. These are known as brown rods. The finer kinds, after the more shrubby or ill-grown rods, termed "ragged," have been rejected, are peeled or buffed. Two methods of stripping are chiefly practised: from the heads (sets) and from the pit. By the former method the rods are left on the ground until spring advances, when a rapid growth of the cambium begins. They are then cut direct from the head and the bark is easily removed by drawing the rods through a bifurcated hand-brake of smooth, well-rounded steel, framed in wood. Improved brakes worked by a treadle strip two rods at a time. For the smaller sizes, rubber brakes are sometimes used and, for the very smallest, the fingers either bare or protected by linen bands. This method ensures a clean-butted unfractured rod, but unless great judgment is exercised in selecting the proper time for cutting the rods will remain double-skinned and the head may bleed. By the "pit" process the green rods are stood upright in shallow pits of water at a depth of about 6 to 9 in. until the sap rises and growth begins, when they are ready for the brake. The defects of this method are that the tops are liable to split in the brake and the butts to remain foul. A third, known as the "pie" system, enables the grower to bridge over the interval, and to keep his workers employed, between the end of the "head" and the beginning of the "pit" strippings.

The willows are cut at the first indication of the sap rising and "couched" in rotten peelings and soil at a slight angle, the butts being on the ground, which should be strewn with damp straw from a manure heap. The tops are covered lightly with rotted peelings and by periodical application of water, fermentation is induced at the bottom, heat is engendered, the leaves force their way through the covering and peeling may begin. Peeling is chiefly done by women and lasts from early May to the middle of July, but a motor peeler has been introduced in some osier grounds. After stripping, the rods are bleached in the sun and stored for sale as white. If the rods are to be buffed they are immersed in large tanks of boiling water from four to six hours. They are then allowed to cool and mellow, are stripped and carefully dried in sun and air and remain dyed a rich tawny brown or buff colour. Brown rods may also be buffed by sinking them in cold water which is heated to boiling point and maintained at that temperature for the requisite period.

In its natural habitat the osier or willow is a dioecious plant reproduced by cross fertilization, but for at least 2,000 years it has been cultivated from cuttings. The stocks have therefore become enfeebled; their cultivation is attended with many disturbing causes—ground vermin, fungoid and insect pests as well as winter floods and spring frosts.

The British ministry of agriculture and fisheries has shown that under suitable conditions improved stocks of basket willows can be produced by cross fertilization and their disease-resisting power strengthened.

In eastern North America the name "red osier" has been applied to *Cornus stolonifera,* one of the shrubby dogwoods.

See W. P. Ellmore, *The Cultivation of Osiers and Willows,* 2nd ed.; also a leaflet (No. 36) on the same subject published gratis by the British ministry of agriculture. (T. O.; X.)

OSIJEK (Germ. ESSEG, Magyar ESZEK), town of Croatia, Yugos. Pop. (1948) 50,398, chiefly Croats and Magyars. It is situated on the Drave, which is there crossed by two bridges, below which the river is navigable by small steamers. The upper or old town contains the fortress, while the lower or new town is the commercial centre.

It has several Orthodox and Roman Catholic churches, Franciscan and Capuchin monasteries, a synagogue, gymnasium, school, hospital, chamber of commerce and law courts. Osijek has a thriving trade in grain, fruit, livestock, plum brandy and timber. There are cotton mills, tanneries and a sugar beet factory, while silk weaving, glass blowing and the making of hats and caps are also carried on.

Osijek owes its origin to its fortress, which existed in Roman times under the name of *Mursia.*

OSIMO, a town and episcopal see (anc. AUXIMUM, *q.v.*), the Marches, Italy, province of Ancona, 10 mi. S. of that town by rail. Pop. (1951) 22,660 (commune). It is on the top of a hill 870 ft. above sea level and it retains a portion of its ancient town wall (2nd century B.C.). The cathedral has a portal with sculptures of the 13th century, an old crypt and a fine bronze font of the 16th century; the town hall contains a number of statues found on the site of the ancient forum and also a few pictures. Silk spinning and the raising of cocoons are carried on.

OSIRIS, one of the principal gods of the ancient Egyptians. *See* EGYPT: *Religion.*

OSISO, an instrument for recording the exact character of vibrations. It has been used for the investigation of electrical phenomena, recording sounds, enabling the totally deaf to understand speech and to speak, studying and eliminating vibration in machinery, determining the recoil action of guns, locating heavy artillery, aeroplanes and vessels, studying heart beats, respiration and other bodily functions, locating oil, ore bodies, etc. The osiso consists of a tiny mirror mounted on two wires and suspended between the poles of a magnet. If a current flows through the wires in a strong magnetic field, they will tend to move, the direction and

extent of the motion depending upon the direction and strength of the current flow. A beam of light, reflected from the mirror, provides a means for making visible the movements of the mirror and for recording them on a photographic film. Every sound produces its own individual wave form, and the meaning of these waves can be read.

(*See* INSTRUMENTS, ELECTRICAL.)

OSKALOOSA, a city of southeastern Iowa, U.S., on federal highway 63, near the Des Moines river and Keomah Lakes State park; the county seat of Mahaska county. It is served by the Minneapolis and St. Louis, and the Rock Island railways. Pop. (1950) 11,095; (1940) 11,024 by the federal census. It is in a farming and coal-mining region, and has a number of important factories. William Penn college, founded in 1873, is located on the northern edge of the city. In the suburb of University park, adjoining it on the east, is Kletzing college. Oskaloosa was settled in 1843, chosen for the county seat in 1844, and chartered as a city in 1853. It was named after a Seminole princess.

OSLER, SIR WILLIAM (1849–1919), British physician, was born at Bond Head, Canada, July 12, 1849, and was educated at Trinity college school, Port Hope, Trinity College, Toronto, and McGill university, Montreal, where he took the M.D. degree in 1872. He studied medicine in London, Leipzig and Vienna and in 1874 was appointed professor of medicine at McGill university. From 1884 to 1889 he was professor of clinical medicine in the University of Pennsylvania, and from 1889 to 1904 professor of medicine at Johns Hopkins university. In 1905 he was appointed regius professor of medicine at Oxford, where he also served as a curator of the Bodleian library, as a delegate of the University Press and as one of the Radcliffe trustees. In 1911 he was created a baronet. Sir William Osler carried out original and valuable researches on the diseases of the spleen and blood and also made eminent contributions to the study of infections of the heart, of angina pectoris, of malaria and of many minor maladies. Sir William died at Oxford Dec. 29, 1919.

His most important work was *The Principle and Practice of Medicine* (1892, latest edition 1920). He also wrote monographs on *Cerebral Palsies in Children* (1889); and *Chorea and Choreiform Affections* (1894); a volume of essays *Aequanimitas* (1901); and *A Way of Life* (1913).

OSLO (known as KRISTIANIA or CHRISTIANIA from 1624 to 1925), capital of Norway, forming a separate county (*fylke*), and the seat of a bishopric (*stift*). Pop. (1946 census) 285,884. Area, 7 sq.mi. It lies in southern Norway, on the Aker river, at the head of Oslo fjord some 80 mi. from the Skagerrak. The modern city, with its busy, island-studded harbour, lies in a basin surrounded by pine-wooded hills. Before World War II it developed rapidly as the great town of Norway, containing not only the governmental offices, courts and parliament, but the university and the important national theatres and museums. Karl Johans Gate is the chief thoroughfare, with the royal castle and its statue of Karl Johan at the western end, and along its sides some of the leading banks and business houses, the Grand Hotel, the Frederician university (founded in 1811), the National theatre (1899) with its huge statues of Ibsen and Björnson, and the *Storting* (parliament) building (1866). The art museum lies just north of the university; the historical museum nearby. Across the harbour in Bygdö is a special structure housing Nansen's unique exploring ship, the *Fram;* another building for three fine old Viking ships, and the large Folk museum with typical early dwellings, a *stavkirke*, Ibsen's workroom, and exhibits of native handicraft and industry.

The city's population growth (7,500 in 1769; 13,600 in 1815; 134,000 in 1886; about 275,000 in 1943), resulted in the absorption of many of the surrounding communities and the creation of garden suburbs and large modernistic apartment units. At Ullevaal is the largest municipal hospital in the country. High above the city rises Holmenkollen with its famous ski-jump and ski museum. At Tören is a science museum. Still incomplete but in use at the time of the German invasion in 1940 was an impressive new city hall, built in a former slum area on the inner harbour called Pipervik. Immediately to the east is the Akershus fortress, extensive but not kept up to date.

The site of the old city of Oslo lies east of the Aker river. It was founded by Harald Hardrada in 1048, became soon the seat of a bishopric, and in the 14th century was the *de facto* capital. Its period of brilliance was from 1286 to 1350, but it was repeatedly burned and plundered; after complete destruction by fire in 1624 it was left to ruin and the inhabitants were ordered to build Kristiania (named for King Christian IV of Denmark and Norway). On Jan. 1, 1878, the site was incorporated in Kristiania.

Like the other municipalities of Norway, Oslo before 1940 enjoyed a high degree of local autonomy, especially after the charter of 1837. Its Council of 84 elected an executive committee of 21; both were under control of the Labour party after the elections of 1937. The city budget of about $30,000,000 supported farreaching social activities such as the child welfare clinic, mothers' pensions, summer camps for more than 3,000 children, the famous "Oslo breakfast" for school children, economic advisers for housewives, and an employment bureau.

Oslo is well connected by rail and highway with other cities of Norway and Sweden; it is also the chief seaport of a seafaring nation. It ordinarily imports about three times as much as it exports and has floating dock, dry dock and elevator facilities; the harbour is kept ice free. Two railway stations serve the city: Östbanegaard or Hovedbanegaard by the Björvik and Vestbanegaard by the Pipervik. There is a special railway up to Holmenkollen and good tram service. There are two large shipbuilding yards and many factories, mostly concentrated in Sagene, manufacturing woollens, linens, paper, pulp, machinery, brick and tile, flour, condensed milk, margarine, oil, soap, hardware, glass, chemicals, beer and liquors.

Electric power is supplied by a huge project at Solbergfoss on the Glommen river.

OSMAN ('UṢMĀN), the usual form of the Arabic name 'OTHMAN, as representing the Turkish and Persian pronunciation of the name. It is used, therefore, for (1) the founder of the Osmanli or Ottoman dynasty, Osman I., who took the title of sultan, ruled in Asia Minor, and died in 1326, and (2) the sixteenth sultan Osman II., who reigned 1616–1621. (*See* TURKEY: *History;* OTHMAN.)

OSMAN (1832–1900), Turkish pasha and mushir (field marshal), was born at Tokat, in Asia Minor, in 1832. Educated at the military academy at Constantinople, he entered the cavalry in 1853, and served under Omar Pasha in the Russian War of 1853–56, in Wallachia and the Crimea. Appointed a captain, in the Imperial Guard, he distinguished himself in the campaigns of the Lebanon in 1860 and of Crete in 1867 to 1869, and was promoted lieut.-colonel. He served under Redif Pasha in suppressing an insurrection in Yemen in 1871, was promoted major-general in 1874, and general of division in 1875. Appointed to command the army corps at Widin in 1876 on the declaration of war by Serbia, he defeated Tchnernaieff at Saitschar and again at Yavor in July, invaded Serbia and captured Alexinatz and Deligrad in October, when the war ended. Osman was promoted to be mushir, and continued his command at Widin.

When the Russians crossed the Danube in July 1877, Osman moved his force to Plevna, and, with the assistance of his engineer, Tewfik Pasha, entrenched himself on the right flank of the Russian line of communication, and gradually made the position a most formidable one. He repulsed the three assaults of the Russians and after being closely invested, held the position until Dec. 9, when, compelled to cut his way out, he was severely wounded and forced to capitulate. This famous improvised defence delayed the Russians for five months, and entailed their crossing the Balkan range in the depth of winter after the third battle of Plevna. The sultan conferred on Osman the Grand Cross of the Osmanie and the title of "Ghazi" (victorious), and, when he returned from imprisonment in Russia, made him commandant of the Imperial Guard, grand-master of the artillery and marshal

of the palace.

In Dec. 1878 he became war minister, and held the post, with a small break, until 1885. He died at Constantinople on April 14, 1900.

OSMANLI, the tribal name of the Turks of the Ottoman empire. The Osmanli include a heterogeneous group of peoples, the original conquering Osmanli having mixed very considerably with the conquered peoples, until physically they have ceased to have a definite separate existence.

OSMIUM, a chemical element found in small quantities in platinum ores but obtained chiefly from the mineral osmiridium by the method of Deville and Debray; together with iridium it was first isolated by Smithson Tennant in 1803 (symbol Os, atomic number 76, atomic weight 190.8). Osmiridium is fused with metallic zinc, the excess of zinc is dissolved in hydrochloric acid and the residue ignited with a mixture of barium nitrate and barium peroxide. When cold, the mass is finely powdered and treated with cold dilute hydrochloric acid in a stoppered bottle; this is necessary as osmium is present in the form of volatile tetroxide. After all action has ceased, nitric and sulphuric acids are added, the mixture is well shaken and the barium sulphate allowed to deposit. The liquid is then distilled, when the volatile osmium tetroxide passes over in an almost pure state. The residue from the distillation is concentrated, ammonium chloride is added, and ammonium iridium chloride $(NH_4)_2IrCl_6$ (together with a little ruthenium) is precipitated. Another method of obtaining osmium from osmiridium is to heat the alloy mixed with common salt in a slow stream of chlorine. The sodium osmichloride, Na_2OsCl_6, produced is extracted with water; sal ammoniac is added to precipitate sparingly soluble ammonium osmichloride, $(NH_4)_2OsCl_6$, which on gentle ignition leaves a residue of spongy osmium. (*See* also RUTHENIUM.)

Osmium in the massive state is a metal of a bluish-white colour. It can be obtained crystalline by alloying any of its forms with metallic tin and subsequently removing the tin by means of hydrochloric acid. It has a specific gravity of 22.48, and melts at about 2,700° C., although it begins to volatilize at a lower temperature. It is a very hard metal, especially when combined with iridium, and the alloy was at one time used extensively for tipping gold pens, but for this purpose cheaper alloys are now employed free from platinum metals and generally having tungsten for their basis. It is not suitable in alloys with other platinum metals for high-temperature work, for, owing to the ease with which it oxidizes, it causes the alloy to disintegrate.

Osmium forms several oxides of which four are known with certainty, namely, OsO, Os_2O_3, OsO_2 and OsO_4, while OsO_3 is present in the metallic osmates. The lower oxides are unimportant. *Osmium tetroxide,* OsO_4, known in commerce under the name of osmic acid, can readily be obtained in a state of purity, and is the source from which other osmium compounds are generally prepared. If metallic osmium in any form is heated in a tube in a current of air, or preferably oxygen, to a bright red heat, combination takes place and a yellowish liquid, OsO_4, condenses in the cold part of the tube, afterward crystallizing in yellowish needles which melt at 40° C.; the liquid boils at 100° C. giving a colourless vapour. Traces of the vapour of osmium tetroxide have a very strong odour somewhat resembling that of chlorine. The vapour is poisonous and exceedingly corrosive and attacks animal membranes vigorously, becoming reduced and leaving a deposit of metallic osmium. In small quantities the physiological effect is transitory but larger quantities entail serious consequences. It is largely used for preparing microscopic slides as it acts preferentially on certain portions of tissue, staining them black. If alcohol is added to OsO_4 dissolved in caustic potash, the solution becomes red and on concentration potassium osmate, $K_2OsO_4{,}2H_2O$, crystallizes out. This salt is stable in neutral solutions but decomposes on acidification, forming OsO_4 and lower oxides. Osmium has several chlorides such as $OsCl_2$, $OsCl_3$ and $OsCl_4$; these, and especially the last two, have a great tendency to combine with alkaline chlorides producing double chlorides of the form M_3OsCl_6 and M_2OsCl_6. They are readily formed from the tetroxide by the use of suitable reducing agents. Two sulphides of osmium are known, OsS_2 and OsS_4; the latter is formed by the action of sulphuretted hydrogen upon acid solutions of the tetroxide. Qualitatively, osmium is detected by the odour of OsO_4 produced when the metal is ignited in air. A delicate test for OsO_4 is to warm an aqueous solution with thiocarbamide and dilute hydrochloric acid, when a red coloration shows the presence of osmium. (F. E. M.)

OSNABRÜCK, a town and espiscopal see in Lower Saxony, Germany, on the Hase, 70 mi. W. of the city of Hanover, 31 mi. by rail N.E. of Münster, and at the junction of the lines Hamburg–Cologne and Berlin–Amsterdam. Pop. (1950) 109,538. In 888 Osnabrück received the right to establish a mint, a market and a toll-house. Surrounded with walls toward the close of the 11th century, it maintained an independent attitude toward its nominal ruler, the bishop, and joined the Hanseatic league, reaching the height of its prosperity in the 15th century. The older streets contain examples of Gothic and Renaissance domestic architecture. The Roman Catholic cathedral, with its three towers, is a building of the 13th century, partly in the Romanesque and partly in the Transitional style; but it is inferior in architectural interest to the Marienkirche, a Gothic structure of the 14th and 15th centuries. The town hall, a 15th century Gothic building, contains portraits of some of the plenipotentiaries engaged in concluding the peace of Westphalia. Other important buildings are the museum, containing scientific and historical collections; the episcopal palace and the law courts. The lunatic asylum on the Gertrudenberg occupies the site of an ancient nunnery. Linen was formerly the staple product, but it no longer retains that position. The manufactures include machinery, paper, celluloid, chemicals, tobacco and cigars, pianos, cloth and beer. It has large iron and steel works, and coal mines in the neighbourhood. It was bombed repeatedly and very severely during World War II.

OSORNO, a province in south Chile, bounded north along the Río Bueno by Valdivia, east by Argentina, south by Llanquihue and west by the Pacific. Area 3,867 sq.mi.; population (1952) 123,059. The province was created by law Jan. 19, 1940, about two-thirds the territory having been taken from the province of Llanquihue, the remainder from the province of Valdivia. Osorno lies in the temperate rain forest zone of the south, and is divided longitudinally into the three physiographic regions (coastal mountains, interior valley and cordillera) which characterize the majority of the provinces of Chile. The west is sparsely settled, and there are no towns, ports or roads in the region. The central valley, traversed by the Santiago-Puerto Montt line of the State railways, is a productive agricultural and stock-raising region, settled in considerable part by German colonists and their descendants. The valley is integrated by a good network of roads, many of which lead eastward to the lake district. The eastern part of the province is noted for its lakes (especially Ranco, the southern half of which is in Osorno, Puyehue and Rupanco), resorts (Lago Ranco, Salto del Pilmaiquén, Baños de Azufre and Termas de Puyehue), forests and mountains.

Osorno, capital of the province and department of the same name (population 40,120 in 1952), was founded in 1553 and named in honour of the Marqués de Osorno, viceroy of Peru. Centrally located in the valley, Osorno has the distinction of being the only large urban centre in the province, the fourth largest city in south Chile, the gateway to southern Chile's famous tourist region, and the western terminus of the important international route which leads to the Argentine town of San Carlos de Bariloche. The province is divided into two departments, Osorno and Río Negro, the capital of the latter being Río Negro, with a population of but 3,450 in 1952.

OSPREY or **OSPRAY,** a bird of prey of conspicuously marked plumage, the white of its lower parts and head contrasting sharply with the dark brown of the back when it is on the wing. It is the representative of the family *Pandionidae,* closely related to the *Falconidae.* Its special characters are the presence of a reversible outer toe and spicules on the soles of the feet.

The osprey (*Pandion haliaetus*) is one of the most cosmopolitan birds of prey. Where, through abundance of food, it is numerous,

the nests of the fish-hawk (to use its American name) may be placed on trees to the number of 30 close together. Where food is scarcer and the species accordingly less plentiful, a single pair will occupy an isolated rock, as formerly in Scotland. Few birds lay eggs so rich in colouring: their white or pale ground is spotted, blotched or marbled with almost every shade of purple, orange and red, from the most delicate lilac and buff, through violet, chestnut and crimson, to black. The fierceness with which ospreys defend their eggs and young, in addition to the dangerous situation chosen for the aerie, makes the task of robbing the nests difficult. It no longer breeds in Great Britain. The term "osprey," applied to the nuptial plumes of the egrets in the feather trade, is derived from the French *esprit;* it has nothing to do with the osprey bird.

BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

THE OSPREY (PANDION HALIAETUS)

A bird of prey, known in America as the fish-hawk

OSROENE or **OSRHOENE,** a district of northwestern Mesopotamia, in the hill country on the upper Bilechas (Belichus; mod. *Nahr Belik*, Bilikh), the tributary of the Euphrates, with its capital at Edessa (*q.v.*), founded by Seleucus I. About 130 B.C. Edessa was occupied by a nomadic Arabic tribe, the Orrhoei (Plin. v, 85; vi, 25, 117, 129), who founded a small state ruled by their chieftains with the title of kings. After them the district was called Orrhoene (thus in the inscriptions, in Pliny and Dio Cassius), which occasionally has been changed into Osroene, in assimilation to the Parthian name Osroes or Chosroes (Khosrau). The founder of the dynasty is therefore called Osroes by Procop. (*Bell Pers.* i, 17) but Orhāi or Urhāi, son of Hewyā (*i.e.* "the snake"), in the chronicle of Dionysius of Tellmahre; he is no historical personality, but the eponym of the tribe. The kings soon became dependants of the Parthians; their names are mostly Arabic (Bekr, Abgar, *Ma'nu*), but among them occur some Iranian (Parthian) names, as Pacorus and Phratamaspates. Under Tigranes of Armenia they became his vassals, and after the victories of Lucullus and Pompey, vassals of the Romans. Their names occur in all wars between Romans and Parthians, when they generally inclined to the Parthian side; *e.g.*, in the wars of Crassus and Trajan. Trajan deposed the dynasty, but Hadrian restored it. The kings generally used Greek inscriptions on their coins, but when they sided with the Parthians, as in the war of Marcus Aurelius and Verus (A.D. 161–165), an Aramaic legend appears instead. Hellenism soon disappeared and the Arabs adopted the language and civilization of the Aramaeans. This development was hastened by the introduction of Christianity, which is said to have been brought here by the apostle Judas, the brother of James, whose tomb was shown in Edessa. In 190 and 201 we hear of Christian churches in Edessa. King Abgar IX (or VIII) (179–214) himself became a Christian and abolished the pagan cults. Caracalla in 216 abolished the kingdom of Osroene (Dio Cass. 77. 12, 14) and Edessa became a Roman colony. The list of the kings of Osroene is preserved in the Syrian chronicle of Dionysius of Tellmahre, which is checked by the coins and the data of the Greek and Roman authors; it has been reconstructed by A. von. Gutschmid, "Untersuchungen über die Geschichte des Königreichs Osroene," in *Mémoires de l'Acad. de St. Pétersbourg,* t. xxxv (1887). Edessa remained Roman till it was taken by Chosroes II in 608; but in 625 Heraclius conquered it again. In 638 it was taken by the Arabs. (ED. M.)

OSS, an industrial town in North Brabant, Netherlands. Pop. (1940) 17,467. It is the centre of the Dutch margarine industry.

OSSA (mod. *Kissovo, Kissavo*), a mountain (el. *c.* 6,400 ft.) in Larissa, S.E. part of Thessaly, Greece; S. of Olympus, from which it is separated by the valley of Tempe, and N. of Pelion which the Giants are said to have piled on it to scale Olympus.

OSSETE. This member of the northern group forms of Iranian speech was spoken in the area north of the Caucasus. It is the survival of a number of Scythian languages formerly current in S. Russia before the Slav onset. It is divided into two divisions, eastern and western. A number of words in Hungarian indicate an ancient association between the languages.

See Miller, *Grundriss der Iranische Philologie* Vol. I.

OSSETIAN AUTONOMOUS AREAS, two administrative units of Russia. (1) The South Ossetian Area created in 1922 is linked administratively with the Georgian S.S.R. Area 1,429 sq.mi. Pop. (1933) 95,300. (2) The North Ossetian Area created in 1924 is linked administratively with the North Caucasian Area. Area 2,327 sq.mi. Pop. (1939) 328,885.

The Ossetes are descended from the Alans, the strongest and most numerous of the Sarmatian tribes, and their language belongs to the Iranic group of the Aryan tongues. The earliest reference to the Alans is A.D. 35 when, according to Josephus, they occupied the Kuban valley; later they occupied the Don and Dnieper regions, where they joined forces with Germanic tribes in attacks on the Romans. Legend gives the Emperor Maximin a Gothic father and an Alan mother. The Hun invasion swept them from the steppe, but they took refuge in the Caucasus and were probably settled in their present territory in the 5th and 6th centuries. They have been described by some writers as long headed, blue eyed and fair haired, but recent Russian investigators describe them as rather broad headed, with swarthy complexions, dark eyes and hair, and straight noses, their stature being above the average. In the Caucasus they held the grassy passes leading from the sources of the Terek and the Ardon to those of the Rion and the Kura, by which alone horsemen and troops can cross the range in summer, and in the height of their prosperity their flocks whitened the steppe and their vintages were famous. The rude walls and towers of their fortified farms and villages still remain on high and defensible ridges in the mountain fastnesses. Later they formed villages with two storied stone houses, the lower for the cattle and the upper for human habitation, with flat wooden roofs and balconies.

Queen Thamar of Georgia introduced Christianity among them in the 12th century, but later the Kabardians drove them from many of their pastures and Turkish tribes supplanted them in the lower valleys and introduced the Islamic faith within their borders. The Ossetes, however, even in their decline, still held the upper passes, the keys of the Caucasus. The Russian hold on the region began when a small fortress was established at Vladikavkaz in 1784 and the Ossetes were conquered in 1802. Later the famous Georgian military road through the Dariel gorge of the Terek, constructed 1811 to 1864, brought the Ossetes more definitely under Russian rule. For a description of the rich treasures found in the tombs of the Alans, *see* Rostovtseff, M., *Iranians and Greeks in South Russia,* 1922.

Most of the territory of the Ossetes consists of the mountain region of the Caucasus, with snow clad peaks, *e.g.*, the Adai Khokh (15,242 ft.). Numerous streams ultimately join the Terek; in their upper courses they have carved deep valleys. They are of no use for floating timber or for navigation, owing to their rapidity and the numerous falls, but are of great potential value as a source of hydroelectric energy, and a hydroelectric station has recently been built on the Gizeldon. The chief pass is the Mamison, over which goes the Ossetian military road, constructed in 1889. No other good road exists in the whole Ossetian area. A loop from the Black Sea–Caspian railway passes through the north of the territory, with a branch to Alagir and Vladikavkaz. The latter town is the administrative centre for the North Ossetes, but forms a separate administrative division of the North Caucasian Area. Stalinir (formerly Tskinvali), a settlement of 5,809 inhabitants, is the administrative centre of the South Ossetes. The chief range apart from the Central Caucasus, is the Bokovoi Ridge, exceeding a height of 10,000 feet. The average altitude of South Ossetia is 10,000 feet. (*See* CAUCASUS.)

Forest and shrub are general in the region, oak and hardbeam being the prevailing varieties in the north, where timber is exported through Alagir. The forests extend to the upper limit of the limestone gorges, but the crystalline schists are bare of

vegetation. Coniferous forests extend above the oak, hardbeam, ash, maple and lime and alpine meadows with a rich variety of blossoms are found above the tree limit. On the plateau in the north maize gives good harvests and occupies 76% of the sown area; winter wheat, potatoes, fruit, sunflower seed, tobacco and vegetables are also cultivated; the latter find a market in Vladikavkaz and in the tomato-canning factory recently established at Alagir. Milk, meat and cheese, from sheep and goats especially and from cows in some regions, form the staple food of the herdsmen and shepherds. Small patches of summer wheat, barley, oats and potatoes are grown in sheltered spots among the hills, but frost or early snow often spoils the harvest. Unworked coal, naphtha, iron, manganese, graphite, asbestos, wolfram and arsenic exist; the only mineral at present exploited is lead. South Ossetia is essentially a grazing region, with sheep and goats in the east and cattle in the west. It is thinly peopled in comparison with the north, and its population was further diminished by the disastrous war conditions following the 1917 Revolution when many natives left their homes and went northward. Conditions in this region recovered very slowly. Peasant industries include the making of daggers and metal goods, fur caps, leather goods and small metal wares.

There are two main Ossetian dialects, the Iron and the Digor; the South Ossetians call themselves Tualte and speak a dialect related to the Iron group. Ossetes form about 85% of the population and Russians and Ukrainians about 12%. The literacy rate among this scattered population in a region of poor communications is low and decreases from north to south. Since the Ossetes received cultural autonomy the Latin script has been adopted and some newspapers and books are now printed in Ossete. School provision is made for less than half the children, mainly for those in the plateau region. The problem of providing education and medical help for the herdsmen and shepherds of the mountain regions is at present unsolved. (R. M. F.)

OSSETIAN LANGUAGE: *see* OSSETE.

OSSETT, a municipal borough in the Dewsbury parliamentary division of the West Riding of Yorkshire, Eng., 2½ mi. W. of Wakefield. Pop. (1951) 14,576. Area 5.2 sq.mi. It lies along a spur of upland about 300 ft. high which forms part of the Aire-Calder divide. In the centre of the heavy woollen district, its chief industries are the manufacture of textiles (mainly shoddy and mungo) and mining. Others include engineering, leatherworking and rubber moulding. Ossett is mentioned in Domesday book and suffered devastation under William the Conqueror. In the 17th century it was visited by plague, but the discovery of medicinal springs to the southeast gave it a temporary attraction. It was incorporated in 1890.

OSSIETZKY, KARL VON (1887–1938), German journalist and pacifist, was born at Hamburg on Oct. 3, 1887. He was the son of a former German army officer who was a member of a germanized branch of the Polish Roman Catholic family of Osiecki. In 1912 he joined the German Peace society (Deutsche Friedensgesellschaft) but was conscripted into the army and served throughout World War I. In 1920, in Berlin, he became secretary of the D.F.G. Convinced that "nothing was more devastating for peace and democracy than the omnipotence of the generals," he helped to found the *Nie Wieder Krieg* organization in 1922. He was associate editor of the daily newspaper, *Berliner Volkszeitung,* and a contributor to *Weltbühne,* a left-wing political weekly. He became editor of *Weltbühne* in 1927, and in a series of articles unmasked the *Reichswehr* leaders' secret preparations for rearmament. Accused of treason, he was sentenced in Nov. 1931 by the Leipzig supreme court to 18 months' imprisonment, but was amnestied in Dec. 1932. On Hitler's accession to power Ossietzky refused to flee abroad, and resumed publication of *Weltbühne.* At the end of Feb. 1933 he was arrested and sent to the Papenburg concentration camp from which, suffering from tuberculosis, he was transferred in May 1936 to a prison hospital in Berlin and a few months later to a public hospital where, however, he remained in custody until his death on May 4, 1938. On Nov. 24, 1936, he had been awarded by the Norwegian *storting* the Nobel peace prize for 1935. Hitler's reply to this was a decree of Jan. 30, 1937, forbidding Germans to accept any Nobel prize in the future.

See A. Williams-Ellis (ed.), ***What Was His Crime? The Case of Carl von Ossietzky*** (London, 1937).

OSSINING, a village of Westchester county, New York, U.S., on the east bank of the Hudson river, 30 mi. above New York city; served by the New York Central railroad. The population was 16,098 in 1950; 1940 federal census, 15,996. Ossining has a fine site, looking over the Tappan Zee and beyond Croton point to Haverstraw bay (expansions of the Hudson), and is surrounded by wooded rolling country. Two beautiful residential villages (Scarborough and Briarcliff Manor) adjoin it on the south and southeast. It is the seat of several private schools and Sing Sing (state) prison is within the village limits. The manufactures are varied, including porous plasters, pills, brass, wire, medical and aviation instruments and maps. The site of Ossining (originally part of the Phillipse manor) was settled about 1700 and the name Sing Sing was taken from the Sin Sinck Indians. The village was incorporated in 1813 and adopted its present name in 1901.

OSSORY (OSRAIGHE), an ancient kingdom of Ireland whose capital was Kilkenny and whose kings maintained their position until 1110. The diocese of Ossory includes Kilkenny and parts of Leix and Offaly. The Church of Ireland diocese was united with those of Ferns and Leighlin in 1832.

OSTADE, the name of two Dutch painters whose father had moved to Haarlem early in the 17th century from the village of Ostade near Eindhoven. The artists were the eldest and youngest sons of a large family.

ADRIAEN VAN OSTADE (1610–85) was born on Dec. 10, 1610, in Haarlem, where he lived throughout his life. He is traditionally supposed to have been a pupil of Frans Hals, and it is possible that both he and his Flemish contemporary Adriaen Brouwer (*c.* 1606–38) were in Hals's studio about 1627, though some sources suggest Salomon van Ruysdael as his master. In 1662 he was president of the painters' guild in Haarlem.

His works won him much popularity during his lifetime and he became a fairly wealthy man. Although Ostade and Brouwer may for a time have been pupils of Hals, the latter's style was not a major influence on either of them, and there is a much closer resemblance between the paintings of the two younger men than between their pictures and those of any older master. Both delighted in scenes of low peasant life, tavern brawls, etc., usually in dimly lit interiors with a single source of light illuminating the principal group. Both treated these themes with a broad and vigorous technique and in a subdued range of colours that at times borders on monochrome, and both used a considerable element of caricature to underline the coarseness of their peasant types. There is little doubt that Brouwer's artistic personality was the stronger and that he was the most important influence in shaping Ostade's style. Ostade's colour schemes in the early period are largely confined to a range of neutral bluish-grays and browns, sometimes enlivened by a single note of more positive colour. Later, from the 1640s onward, he gradually adopted a brighter palette, and his subjects, though still mostly from peasant life, tended to become less violent and grotesque. In the works of his maturity one finds more outdoor subjects, such as figures by a cottage door or peasants merrymaking outside an inn. Although the great majority of his works are genre pieces, he experimented also with religious subjects, portraits and landscapes. He worked in water colour as well as oil, was a spirited draftsman with the pen and produced a number of etchings, of which 50 are known. He was a prolific artist, painting usually on panel and invariably on a small scale, and is well represented in the principal collections of Europe and America. His most important pupils or followers were his brother Isack, Cornelis Bega, Cornelis Dusart and Jan de Groot.

ISACK VAN OSTADE (1621–49) was born in Haarlem, where, as far as is known, he spent the whole of his short life. He was at first a pupil of his brother Adriaen, whose manner he followed so closely that some of his early genre pieces have been confused with the elder Ostade's work. However, he was too accomplished and individual an artist to remain an imitator of his brother, and soon branched out into a style that was more ambitious, both in scale and in complexity of composition. The works of his most distinguished period include a small number of winter landscapes, with sleighers and skaters on the ice, which can be ranked among the finest of all Dutch paintings in this genre, but his most characteristic subjects are those which depict parties of travellers with carts and horses resting outside an inn, in a vein reminiscent of some similar compositions by Salomon van Ruysdael. They show an excellent grasp of design in the disposition of the different groups, together with great vivacity in the treatment of individual figures. His rendering of misty or smoke-laden atmosphere is equally masterly. His work is well represented in the National gallery, London, and the Wallace collection has a fine painting of "A Market Place." Perhaps the most celebrated of the winter scenes is that in the Louvre, Paris. Since he died at such an early age, Isack van Ostade can have had few if any pupils, yet his influence on the succeeding generation of Haarlem painters was by no means negligible. Philips Wouwerman (*q.v.*), in particular, seems to have owed much to him, carrying on his characteristic subject matter of travellers, horses and wayside inns and apparently deriving his favourite motif of the gray horse directly from Ostade's example.

See C. Hofstede de Groot, *Catalogue of Dutch Painters,* vol. iii, (London, 1910). (R. E. W. J.)

OSTASHKOV, a town of Russia in the province of Tver, in 57° 10′ N., 33° 5′ E., on the south shore of Lake Seliger, near the outlet of its waters into a stream that joins the upper Volga

and was at one time thought to be the source of that river. It is in a damp and marshy situation, but became a centre for pilgrims visiting the Stolbenski monastery on an island in the lake. Later the railway passed through the town, and it became the terminus of a telegraph line. Its population (15,660) is mainly occupied in tanning and the making of leather goods, in iron founding and brick making and in fishing on the lake.

OSTEND (Flemish *Oostende*), West Flanders, Belg. Pop. (1947) 49,651. It is the most fashionable seaside resort and the third port of the kingdom. In the middle ages it was strongly fortified and underwent several sieges; notably in 1601–04, when it only surrendered by order of the states to Spinola. The creation in 1722 of the Compagnie de Commerce des Indes seemed to assure a hopeful future to the port of Ostend. But the success obtained caused the envy of neighbouring nations, who forced Emperor Charles VI to revoke the grant made. Under Joseph II Ostend enjoyed another period of commercial prosperity. In the 20th century a new town was created. The digue or parade, constructed of solid granite, extends for more than 3 mi. along the shore in a southerly direction from the long jetty which protects the entrance to the port. A casino and the royal châlet are prominent on the sea front. In the rear of the town is a fine park to which a race course has been added. The modern docks accommodate ships of large tonnage. Apart from these docks Ostend has a very considerable passenger and provision traffic with England, and is the headquarters of the Belgian fishing fleet, estimated to employ 400 boats and 1,600 men and boys. Ostend supplies sea fish and is renowned for its oyster and lobster beds. It has a school of navigation and a fishery training school. There is a daily service from Ostend to Tilbury carrying food produce for England. Ostend is in direct railway communication with Brussels, Cologne and Berlin. It is also the starting point of several light railways along the coast and to the southern towns of Flanders. Ostend was occupied by the Germans for four years during World War I, and was at first, until it was rendered untenable by aerial bombardments, a base for destroyers and submarines. In May 1918 the entrance channel to the harbour and the canal to Ghent and Bruges were blocked to all craft except the smallest submarines by the sinking of the "Vindictive." After the war she was raised and broken up. Parts of the "Vindictive," "Intrepid" and "Thetis" were made into a memorial on the digue.

The city was occupied by the Germans again in World War II.

OSTEND COMPANY. The treaties of Utrecht and of Rastatt (1713–14) at the end of the War of the Spanish Succession transferred the Spanish Netherlands to the house of Austria but maintained Dutch control over the Scheldt and so over the commerce of Antwerp as under the peace of Westphalia (1648). In Ostend, however, the Flemings had a port on the open sea, and from 1715 onward attempts were being made, both by the Ostenders themselves and by foreign adventurers, to exploit its geographical advantages for trading in emulation of the Dutch and English East India companies. These private enterprises led to protests and to the seizure of interloping ships by the Dutch and English companies. But meanwhile the imperial government, prompted to some extent by the schemes of the English adventurer John Colebrooke, was considering a major undertaking on the same lines; and in Dec. 1722 the emperor Charles VI granted a charter for 30 years to a company that was to be based on Ostend to trade to the East and West Indies and Africa (in return for the charter the imperial treasury was to enjoy 3%–6% of the profits). The company founded two settlements in India, the more important of which was Bankibazar on the Hooghly, and trade proved at first highly profitable, particularly as it was able to benefit from extensive smuggling into England. The protests of the English and Dutch companies, whose shares slumped before this competition, were reinforced by those of their governments, who, particularly when Spain gave its support to the venture (1725), were alarmed at its political as well as commercial implications.

Public opinion was aroused, and the United Kingdom parliament declared participation by a British subject in the Ostend company to be a criminal offense. In consequence of this alarm the fate of the new company loomed large in the diplomacy of the great powers from 1725 to 1731. On this, as well as on other more vital issues, Great Britain, France, the United Provinces and, at first, Prussia allied themselves against the emperor and Spain, later joined by Russia and by Prussia (who abandoned its former allies). In 1727, however, the emperor's desire for international recognition of the pragmatic sanction ensuring the succession of his daughter Maria Theresa led him to agree to suspend the company for seven years; and in 1731, under the treaty of Vienna, the company was dissolved in return for the recognition of the pragmatic sanction. The suspension of its charter did not immediately end the company's activities. Attempts by the Danish company to attract its members were checked by the vigorous representations of Great Britain, the United Provinces and France, but at Bankibazar the servants of the defunct company raised the emperor's flag and continued to carry on their trade until in 1744 the settlement fell to a siege by the *faujdar* of Hooghly.

See M. Huisman, *La Belgique commerciale sous l'empereur Charles VI: la Compagnie d'Ostende* (Brussels, 1902). (L. S. Sd.)

OSTEND MANIFESTO, a document issued (Oct. 18, 1854) by James Buchanan, J. Y. Mason and Pierre Soulé, U.S. ministers respectively to Great Britain, France and Spain, who had met by Pres. Franklin Pierce's orders at Ostend, Belg., to discuss and adopt measures for diplomatic action at Madrid on the subject of alleged injuries by Spain to U.S. commerce with Cuba. The manifesto recommended that "the United States ought, if practicable, to purchase Cuba as soon as possible," and, if Spain should refuse to sell, then "by every law, human and divine, we shall be justified in wresting it from Spain if we have the power." W. L. Marcy, secretary of state, disavowed the document.

OSTEOARTHRITIS. Osteoarthritis (synonyms: hypertrophic, degenerative and senescent arthritis) is a degenerative disease of the cartilages of the joints which often is eventually accompanied by hypertrophic changes of marginal and subchondral bone. Primary osteoarthritis develops insidiously and more or less spontaneously in persons who are more than 40 or 45 years of age; secondary osteoarthritis is the name given to the osteocartilaginous changes in joints resulting from various injuries (acute accidental) or chronic irritations (occupational or postural stresses or congenital or acquired malformations of joints), or it may refer to the secondary osteocartilaginous reactions which may occur late in the course of various forms of arthritis (gouty, rheumatoid, suppurative and so forth). Osteoarthritis in persons who are less than 35 or 40 years of age is usually of the secondary type and generally affects only one or two joints; osteoarthritis in persons who are more than 45 or 50 years of age is usually of the primary type and may affect several (but not many) joints, particularly knees, cervical or lumbar vertebral joints and, in women especially, the terminal joints of fingers (Heberden's nodes). Human cartilage appears to have an inherent durability which allows it to remain essentially unimpaired for 40 or 50 years of ordinary wear and tear. What causes the cartilages to begin to degenerate in almost everyone about the age of 45 or 50 years is not exactly known. The chief factors are senescence of tissue (aging of cartilage) and the mechanical irritations from simple wear and tear. The factor of wear and tear alone cannot explain the condition because in many persons the joints affected are not those which have been used or irritated most or those which have carried the most weight; thus, the incidence of osteoarthritis of the terminal joints of fingers (Heberden's nodes) is not abnormal among typists, needleworkers, pianists and others who use the finger joints excessively. Nevertheless, once a joint is affected, mechanical irritations from excessive use, weight bearing and so forth, are important secondary factors which aggravate the condition. Unproved and largely unsupported are the theories that the cartilage degenerates because of arteriosclerosis of the blood vessels which nourish the joints, or because of endocrine or metabolic disorder or infection.

Premature primary osteoarthritis affecting several joints occasionally occurs spontaneously without special injury or undue irritation in certain persons aged only 15 to 35 years who presumably have inherited poor cartilages. The hereditary factor in primary osteoarthritis is also noticeable when Heberden's nodes rather regularly and sometimes prematurely affect several generations (sometimes both male and female members) of certain families.

Many, indeed most, persons who have osteoarthritis have no symptoms; the condition is often discovered incidentally in roentgenograms ordered because of other conditions. Among the persons who have symptoms the disability is mild in most, moderate in some, crippling in very few. Some affected joints are often painful for a while but later are painless. Few if any constitutional reactions accompany the disease which is essentially limited to joints and does not affect other tissues or bodily systems except for some associated transitory stiffness of musculotendinous structures. The condition should be regarded merely as one of the annoying but usually minor disabilities of advancing years.

Because in osteoarthritis synovial membranes are not inflamed or significantly affected, no "plastering membranes" form within joints to fix them, hence no permanent stiffness or fixation (ankylosis) occurs. Thus, a chief remedy is reassurance for the patient that he does not have one of the crippling progressive forms of arthritis or one which is likely to cause serious disability. Moderation in the use of affected joints, their protection from undue irritation (including that from obesity) and the philosophic acceptance by the patient of a somewhat lowered level of physical activity are sometimes the only measures required to obtain comfort. Application of heat and other physical remedies are helpful. For notably affected hips a surgical operation which interposes a metal or plastic cup between affected cartilages appears useful. Of little or no value are such remedies as concentrated vitamins, sulphur, gold, endocrine products, vaccines, roentgen therapy.

Athletic injuries to knees and injuries or malformations of hips provide common causes for secondary osteoarthritis. Articular cartilages are damaged: adequate healing may occur, or late osseous reactions may result. Protection against further mechanical irritations and sometimes surgical repair of damaged joints are required. (P. S. H.)

OSTEOLOGY, that part of the science of anatomy which has for its subject the structure, gross and minute, of the bones and the skeleton (*see* Anatomy; Connective Tissues; Skel-

ETON; etc.).

OSTEOPATHY. According to its advocates, osteopathy is a system of health and healing founded on the theory that the living body is a vital machine that will make the remedies necessary to protect itself against disease as long as it is in correct mechanical adjustment. In addition, osteopathy insists upon a wholesome physical and mental environment, good food, proper exercise and rest, and pure air and water.

Structural derangement is considered as the most important underlying disease cause. What is called a "lesion" may be in bony, muscular, ligamentous, fascial or other tissue. For example, in the bony "lesion," a joint usually lacks free movement. This stiffness may come from injury, strain, inflammation, infection, reflexes or other causes. The resultant lack of normal movement in surrounding tissues allows blood and lymph to stagnate, causing acidosis, irritating nerves which pass that way, and through them affecting the functions of various organs including blood vessels. The oedema and swelling and the contraction of muscles may also affect, by pressure or otherwise, the nerves, arteries and veins. Not only is there said to be a resultant interference with the body's ability to make its own serums and antitoxins to fight infectious disease processes, but "lesions" also produce positive suffering and disease in the form of neuritis and neuralgia, lumbago and sciatica, foot troubles and disturbances of the special senses and of the functions of the various organs including endocrine and other glands.

Osteopathic diagnosis comprises physical examination of the entire body, its distinguishing feature being an intensive search for and study of the lesions described above. There is physical, chemical and microscopic study of secretions and excretions and, if necessary, of tissues, and the use of the X-ray, basal metabolism apparatus and other scientifically accepted appliances.

Osteopathic therapy is based on the specific manipulative removal of the "lesion" already discussed. It includes also correction of hygienic, dietetic, environmental and psychic conditions; surgery for fractures and lacerations, and the removal of abnormal growths or organs so diseased as to be dangerous to life; obstetrics; and the administration of antidotes for poisons.

The American School of Osteopathy was organized at Kirksville, Mo., in 1892. Later there were other recognized colleges at Los Angeles, Calif., Kansas City, Mo., Des Moines, Ia., Chicago and Philadelphia. At the beginning, when the standards of medical education were low, the length of the course was two years. By about 1916, all the colleges required a high school education followed by four standard college years in osteopathy.

Osteopathy was promulgated by A. T. Still (*q.v.*). What is now the American Osteopathic association was organized in 1897. Its headquarters are in Chicago. It publishes a *Journal* and four other monthly periodicals. There are state, provincial and local societies, British, Canadian, New England, eastern, middle-Atlantic and western associations, the Osteopathic Women's National association and several societies of specialists. Osteopathy is regulated by law throughout the United States and most of Canada. In a majority of states examination for licence to practise is in the hands of examining boards composed of osteopathic physicians. In several states there is no legal distinction between "doctor of osteopathy" and "doctor of medicine," while in others osteopathic practice is somewhat restricted.

Many osteopathic physicians have served and are serving on state and local health boards.

In Great Britain, though osteopathy is not recognized or regulated by law, the British Osteopathic association admits to membership graduates of recognized osteopathic colleges.

OSTERMAN, ANDREI IVANOVICH, COUNT (1686–1747), Russian statesman, born at Bochum, Westphalia, was a student at Jena, but fled to Holland after a duel and became secretary to Vice-Adm. Cornelis Cruys, who took him to Russia in 1704. Having acquired a good knowledge of Russian, Osterman was in 1708 appointed interpreter at the Russian foreign office and in 1710 was given the rank of secretary. He rapidly proved his efficiency both at the tsar's headquarters and on missions abroad. In 1711 he assisted the vice-chancellor Petr Pavlovich Shafirov in the peace negotiations with the Turks after Peter's disaster on the Pruth. At the Aland peace congress in 1718, Osterman represented Russia together with Gen. J. D. Bruce, but in fact he played the leading part even before 1719, when he went to Sweden in an attempt to persuade the Swedes to accept the Russian conditions. For the successful conclusion of the peace treaty at Nystad in 1721, Osterman was created baron. Two years later he signed a favourable treaty with Persia and was given the post of vice-president of the reorganized foreign office. Although Osterman was also consulted on internal problems as in the case of the reorganization of the foreign office in 1720, foreign affairs remained his special sphere under Peter. Later, however, his influence made itself felt in all affairs of the state. Under Catherine I (1725–27) Osterman was vice-chancellor, member of the supreme secret council, postmaster general and president of a special commission for commerce, which posts gave him not only complete control over foreign affairs but also occasion to introduce financial and economic measures. He was also governor to the future tsar Peter II, retaining this post even after the latter's accession in 1727. Osterman's shrewd behaviour in 1730 during the abortive attempt to curtail the powers of the empress Anne secured his further career; he was created count and was from 1731 on a member of the new cabinet of ministers. In 1740, after Anne's death, Osterman was given the post of admiral-general and, in addition to foreign affairs, took over naval matters (which had preoccupied him earlier). Toward the end of Anna Leopoldovna's regency (1741) some people considered him as being the actual ruler. This steady ascendancy during the period of favourites was due to his great knowledge and experience and to the skill with which he adapted himself to changes and paved his way with intrigues. However, his foreign policy was consistently based on the alliance with Austria. The two costly wars that ensued, the War of the Polish Succession (1733–35) and the war against Turkey (1735–39) raised Russia's prestige; but because of the political situation the Belgrade treaty (1739) brought only moderate gains. Moreover, intent on avoiding warfare on two fronts, Osterman had restored to Persia the conquests made by Peter. Anglo-Russian relations improved as a result of the commercial treaty concluded in 1734, but Osterman's firm adherence to the Pragmatic Sanction brought Russia into conflict with Austria's enemy, France, and this proved fatal for him personally. The French ambassador J. J. Trotti, marquis de La Chétardie, was behind the coup d'état of 1741 in favour of Elizabeth, whom Osterman had consistently neglected. Osterman was tried and condemned on charges of interfering with the imperial succession, reprieved on the scaffold and banished to Siberia (1742), where he died five years later.

OSTERODE (OSTRODA), Poland, formerly a town in East Prussia, Ger., 75 mi. N.E. of Thorn, on Lake Drewenz, at the junction of lines to Memel, Elbing and Neidenburg. Pop. (1946) 6,769. It has a castle built in 1270 by the Teutonic knights, to whom the town owes its birth. Osterode trades in grain and timber.

OSTERODE, a town in the Prussian province of Hanover, at the south foot of the Harz mountains, 34 mi. N.W. of Nordhausen by rail. Pop. (1933) 8,743. The church of St. Aegidius was founded in 724 and rebuilt after a fire in 1578. The dukes of Brunswick-Grubenhagen made Osterode their residence from

1361 to 1452. There are manufactures of woollen goods, cigars, casks and leather, and iron foundries, tanneries, dyeworks and gypsum quarries. In recent years Osterode has become celebrated as a health resort.

OSTIA, an ancient town and harbour of Latium, Italy, at the mouth of the river Tiber, on its left bank. It lies 14 m. S.W. from Rome by the Via Ostiensis, a road of very ancient origin followed by the modern road which preserves some traces of the old pavement and remains of several ancient bridges, until the construction of a new motor road to Ostia Mare. It was said to be the first colony ever founded by Rome—according to the Romans themselves, by Ancus Martius—and took its name from its position at the mouth (*ostium*) of the river. Excavations have, however, brought to light nothing earlier than the 4th century B.C., the date of a small rectangular fort, measuring 200 by 125 yd., built of hewn blocks of volcanic stone, which may have been in Virgil's mind when he wrote his description of the fortified camp which Aeneas founded at the Tiber mouth. It was out of this fort that the city developed the establishment of the salt-marshes (*salinae—see* SALARIA, VIA) which only ceased to exist in 1875. We learn much as to its cults, magistrates and trade guilds (for the last *see* J. P. Waltzing, *Les Corporations professionelles* [Brussels and Liège]) from the large number of inscriptions found. The city was divided into five regions. Vulcan was the most important deity worshipped at Ostia, and the priesthood of Vulcan was held sometimes by Roman senators. The Dioscuri, too, as patrons of mariners, were held in honour. Later we find the worship of Isis and of Cybele, the latter being especially flourishing, with large corporations of *dendrophori* (priests who carried branches of trees in procession) and *canephori* (basket-carriers); the worship of Mithras, too, had a large number of followers. There was a temple of Serapis at Portus. At Portus a considerable number of Jewish inscriptions in Greek have come to light. In the 4th century Ostia began to be abandoned while the importance of Portus increased.

Until Trajan formed the port of Centumcellae (Civitavecchia) Ostia was the best harbour along the low sandy coast of central Italy between Monte Argentario and Monte Circeo. It is mentioned in the history of the year 354 B.C. as a trading port, and became important as a naval harbour during the Punic Wars. Its commerce increased with the growth of Rome, and this, and the decay of agriculture in Italy, which obliged the capital to rely almost entirely on imported corn (which was, from 267 B.C. onwards, under the charge of a special quaestor stationed at Ostia), rendered the possession of Ostia the key to the situation on more than one occasion (87 B.C., A.D. 409 and 537). Ostia, however, was by no means an ideal harbour; the mouth of the Tiber is exposed to the south-west wind, which often did damage in the harbour itself; in A.D. 62 no less than 200 ships with their cargoes were sunk, and there was an important guild of divers (*urinatores*) at Ostia. The difficulties of the harbour were increased by the continued silting up, produced by the enormous amount of solid material brought down by the river. Even in Strabo's time the harbour of Ostia had become dangerous.

Caesar had projected remedial measures, but it was only under Claudius that the problem was approached. He constructed a large new harbour on the right bank, 2½ m. N. of Ostia, with an area of 170 ac. enclosed by two curving moles, with an artificial island, supporting a lofty lighthouse, in the centre of the space between them. This was connected with the Tiber by an artificial channel, and by this work Claudius, according to his inscriptions of A.D. 46, freed the city of Rome from the danger of inundation. The harbour was named by Nero Portus Augusti.

Trajan found himself obliged in A.D. 103, owing to the silting up of the Claudian harbour and the increase of trade, to construct another port further inland—a hexagonal basin enclosing an area of 97 ac., with enormous warehouses and docks attached, communicating with the harbour of Claudius and with the Tiber by means of the channel already constructed by Claudius, which was prolonged so as also to give direct access to the sea. This became blocked in the middle ages, but was reopened by Paul V. in 1612, forming the right arm of the Tiber, by which navigation is carried on at the present day, and is known as the Fossa Trajana. The island between the two arms Procopius calls Insula Sacra (it is still named Isola Sacra).

Ostia thus lost a considerable amount of its trade, but its importance still continued to be great. The 2nd and 3rd centuries, indeed, are the high-water mark of its prosperity: and it still possessed a mint in the 4th century A.D. The first bishop of Ostia of whom we have knowledge dates from A.D. 313, and the first bishop of Portus from about the same time. Both sees exist; the former is held by the dean of the College of Cardinals.

During the Gothic wars, trade was confined to Portus and the ravages of pirates led to the gradual abandonment of Ostia. Gregory IV. constructed in 830 a fortified enceinte, called Gregoriopolis, in the eastern portion of the ancient city, and the Saracens were signally defeated here under Leo IV. (847–856). The battle is represented in Giulio Romano's fresco from Raphael's design in the Stanza dell' Incendio in the Vatican.

In the middle ages Ostia became a quarry for the cathedral of Orvieto, etc., some of its marbles being conveyed by the Pisans as far as Sardinia. Later it regained something of its importance owing to the silting up of the right arm of the Tiber. In 1483–1486 Giuliano della Rovere (nephew of Pope Sixtus IV., and afterwards himself Pope Julius II.) caused the castle to be erected by Baccio Pontelli, a little to the east of the ancient city. It is built of brick and is one of the finest specimens of Renaissance fortification, and exemplifies especially the transition from the old girdle wall to the system of bastions: it still has round corner towers, not polygonal bastions. An agricultural colony, founded after 1875, and consisting mainly of cultivators from the neighbourhood of Ravenna, has produced a great change for the better in the condition of the place. The modern village is part of the commune of Rome. The marshes have been drained, and a pumping station erected near Castel Fusano. An electric railway has been constructed from Rome to Ostia and thence to the sea-bathing resort of Ostia Mare.

Excavations on the site of Ostia were only begun towards the close of the 18th century, and no systematic work was done until 1854, when under Pius IX. a considerable amount was

done (the objects are now in the Lateran museum). The Italian Government laid bare many of the more important buildings in 1880–89: and resumed work in 1907. Owing to the fact that the site is largely covered with sand and to the absence of any later alterations, the preservation of the buildings excavated is very good, and Ostia is, with the exception of Pompeii, the best example in Italy of a town of the Roman period, while its houses, the massive concrete walls of which were faced with brick and reticulate work (both as a rule left unplastered on the outside) rose to a height of three or four storeys and had balconies and

numerous windows. They were frequently planned like modern apartment houses, and show us what the ancient Roman *insula* or block was. On the east the site is approached by the ancient road from Rome, flanked by tombs. It entered the enceinte of the 1st century B.C. (*see* plan) by a gate still preserved. This wall enclosed an irregular area far larger than that of the 4th century fort, extending down to the ancient coast line and the continuation of the road forms the main street of the town. A considerable part of it had porticoes on each side. On the right (N.) are some small well-preserved thermae, and the barracks of the firemen (*vigiles*), a special cohort of whom was stationed here. On one side of the central courtyard of the latter building is a chapel with inscribed pedestals for imperial statues (2nd and 3rd century A.D.) and a well-preserved black and white mosaic representing a sacrifice.

To the south-west is the theatre, an area 265 ft. square surrounded by colonnades, in which were placed the offices of the various *collegia* or guilds of boatmen, raftmen and others, which had a special importance at Ostia; the names of the guilds may still be read in inscriptions in the mosaic pavements of the chambers. In the centre of the area are the substructions of a temple, and on the south-east side are the remains of the theatre, built in the early imperial period, restored by Septimius Severus in 196–197 and again in the 4th or 5th century. To the south-west of the theatre are the remains of four small temples, one dedicated to Venus, and a well-preserved Mithraeum, with mosaics representing the seven planets, etc. To the south-west again is the conspicuous brick cella of a lofty temple, on arched substructures, hitherto supposed to be that of Vulcan, but more probably the Capitolium or temple of Jupiter, Juno and Minerva, with a threshhold block of *africano* (Euboean) marble over 15 ft. long; from it a street over 20 ft. wide leads north-west to the river. It is flanked on each side by well-preserved warehouses, another group of which, surrounding a large court, lies to the south-west. Further still are the well-preserved Horrea Epaphroditiana et Epagathiana, a large private warehouse. Hence an ancient road, leading between warehouses (into which the Tiber is encroaching), in one room of which a number of well-preserved large jars may be seen embedded in the floor, runs close to the river to a large private house with thermae, in which fine mosaics were found: it (groundlessly) bears the name of "imperial palace." Farther to the south-west are remains of other warehouses, and (possibly) of the docks—long narrow chambers, which may have served to contain ships. The mediaeval Torre Bocacciana marked approximately the mouth of the river in Roman times.

The south-eastern portion of the city has been excavated only partially. Opposite the Capitolium is the Forum, with remains of a temple of Rome and Augustus, a basilica (much destroyed by mediaeval plunderers), the curia, etc. To the south-west of this are the remains of the temple of Cybele, with a portico. This lay close to the commencement of the Via Severiana (*see* SEVERIANA, VIA), and the line of tombs which flanked it soon begins. Farther south-east, a line of sand dunes, covering the ruins of ancient villas, marks the coast line of the Roman period.

See G. Calza, *Ostia* (trans. by R. Weeden Cooke, 1926), and reff. (T. A.)

OSTIAKS or **OSTYAKS,** a tribe who inhabit the basin of the Ob in western Siberia. The so-called Ostyaks of the Yenisei speak an entirely different language. The trans-Uralian Ostiaks and Samoyedes are probably identical with the Yugra of the Russian annals. During the Russian conquest their abodes extended much farther south than now, 41 of their fortified places having been destroyed by the Cossacks in 1501, in the region of Obdorsk alone. Remains of these "towns" are still to be seen at the Kunovat river, on the Ob 20 m. below Obdorsk and elsewhere. Those on the Irtysh are mostly settled, and have adopted the manner of life of Russians and Tatars. Those on the Ob are mostly nomads, and own large herds of reindeer. The Ob Ostiaks are russified to a great extent. They live almost exclusively by fishing, buying from Russian merchants corn for bread.

The Ostiaks call themselves As-yakh (people of the Ob), and it is supposed that their present designation is a corruption of this name. By language they belong with the Voguls to the East Ugrian branch of the Ugrian division of the Ugro-Finnish section of the Ural-Altaic languages. Three or four leading dialects can be distinguished.

The Ostiaks are middle-sized, or short. The skull is roundish, mostly of moderate size and height. The hair is dark and soft for the most part, fair and reddish individuals being rare; the eyes are dark, generally narrow; the nose is flat and broad; the mouth is large and with thick lips; the beard is scanty. Mongoloid traits are more strongly pronounced in the women than in the men. The purest type is found among the fishers on the Ob, the reindeer-breeders of the tundra being largely intermixed with Samoyedes. They are very skilful in carving wood and bone, tanning (with egg-yolk and brains), preparation of implements from birch-bark, etc. Some of their carved or decorated bark implements show considerable artistic skill. Christianity has made some progress among them, but their ancient pagan observances are still retained.

For customs, religion, etc., see *Journal de la Société Finno-Ougrienne,* particularly papers by Sirelius and Karjalainen, and the papers by Munkácsi, Gennep, Fuchs and others in the *Revue orientale pour les études Ouralo-Altaïques;* Patkanov, *Die Irtysch-Ostiaken und ihre Volkspoesie* (1900); Patkanov, *Irtirsch-Ostjaken und ihre Volkspoesie* (1897–1900); Papay, *Sammlung ostjakischer Volksdichtungen* (1906); M. Czaplicka, *Aboriginal Siberia* (1914).

OSTRACISM, a political device instituted as a constitutional safeguard for the Athenian democracy. Its effect was to remove from Athens for a period of ten years any person who threatened the harmony and tranquillity of the body politic. In the sixth prytany (*see* PRYTANEUM AND PRYTANIS) of each year the representatives of the Boulē asked the Ecclesia whether it was for the welfare of the state that ostracism should take place. If the answer was in the affirmative, a day was fixed for the voting in the eighth prytany. No names were mentioned, but two or three names at the most could have been under consideration. The people met, not as usual in the Pnyx, but in the Agora, in the presence of the archons, and recorded their votes by placing in urns small fragments of pottery (*ostraka*) on which they wrote the name of the person whom they wished to banish. Ostracism did not take effect unless ten thousand votes in all were recorded. The ostracised person was compelled to leave Athens for ten years, but he was not regarded as a traitor or criminal. When he returned, he resumed possession of his property and his civic status was unimpaired. The adverse vote simply implied that his power was so great as to be injurious to the state. Ostracism must therefore be carefully distinguished from *exile* in the Roman sense, which involved loss of property and status, and was for an indefinite period (*i.e.,* generally for life). At the same time it was strictly unjust to the victim, and a heavy punishment to a cultured citizen for whom Athens contained all that made life worth living. Its political importance really was that it transferred the protection of the constitution from the Areopagus to the Ecclesia. It was later replaced by the *Graphē Paranomōn.*

The object was primarily to get rid of the Peisistratid faction without perpetual recourse to armed resistance. Aristotle's *Constitution of Athens* (22) gives a list of ostracized persons, the first of whom was a certain Hipparchus of the Peisistratid family (488 B.C.). This, however, may conceivably be simply the list of those recalled from ostracism at the time of Xerxes' invasion, all of whom must have been ostracized less than ten years before 481 (*i.e.,* since Marathon). With the end of the Persian Wars, the original object of ostracism was removed, but it continued in use for forty years and was revived in 417 B.C. It then became a mere party weapon, and the farcical result of its use in 417 in the case of Hyperbolus led to its abolition. Such a device inevitably lent itself to abuse (*see* Aristotle, *Pol.* 38, 1284 b. 22).

OSTRACODA, a subclass of the Crustacea (*q.v.*) comprising minute forms found in fresh water and in the sea, pelagic and bottom dwelling; a few may be parasitic; several live only in water held by the leaves of epiphytes, or in moist debris in holes in trees. Of their food habits little is known. Many are omniv-

OSTRACODS

1. *Halocypris cornuta* (Muller), anterior view. Length 3.2-3.5 mm Atlantic ocean. Order Myodocopa, family Halocypridae (after Muller)
2. *Cypria dentifera* (Sharpe), lateral view. Length 0.69 mm. Found in fresh-water ponds of the eastern United States. Order Podocopa, family Cypridae (after Sharpe)
3. *Halocypris cornuta* (Muller), lateral view
4. *Cythere lobiancoi* (Muller), female, dorsal view. Length 0.48 mm. Mediterranean sea. Order Podocopa, family Cytheridae (after Muller)
5. *Cypridina castanea* (Brady), male, lateral view. Length 4-6 mm. Atlantic and Indian oceans. Order Myodocopa, family Cypridinidae (after Muller)
6. *Cythere diffusa* (Müller), female, dorsal view. Length 0.49-0.52 mm. Mediterranean sea. Order Podocopa, family Cytheridae (after Muller)
7. *Cythereis ornata* (Muller), male, lateral view. Length 0.98 mm. Mediterranean sea. Order Podocopa, family Cytheridae (after Muller)
8. *Gigantocypris agassizii* (Muller), female, anterior view. Length 23.0 mm. Pacific and Atlantic oceans. Order Myodocopa, family Cyprinidae (after Muller)
9. *Conchoecia atlantica* (Lubbock), female, lateral view. Length 3.3-4 8 mm. Atlantic, Pacific and Indian oceans. Order Myodocopa, family Halocypridae (after Muller)
10. *Gigantocypris agassizii* (Müller). Lateral view (after Müller)

orous, some carnivorous and others feed on aquatic plants and diatoms. The Ostracoda are distinguished by having the body and limbs completely enclosed in a bivalve shell. They are remarkable for having a smaller number of appendages than any other Crustacea, there being not more than four pairs and sometimes only two pairs of limbs behind the mandibles. The antennules and antennae are used for swimming or creeping. The mandibles have a large palp, often biramous and sometimes leglike. The remaining limbs are very varied in form but some of them are usually leglike and used in locomotion.

FRESH-WATER OSTRACOD (PIONOCYPRIS VIDUA) ENLARGED
A. External appearance. B. Appendages after removal of left valve shell; left, antennule and antenna; centre mouth-parts, and behind them to the right, two leglike appendages

The breeding habits of the ostracods present several features of interest. Parthenogenesis is common, at least among the freshwater species, in many of which males are rarely seen; while in some species they have not yet been discovered. A colony of a species of *Cypris* has been kept in an aquarium for more than 30 years and during the whole of that time no males made their appearance, the colony reproducing exclusively by parthenogenesis. In some Ostracoda the threadlike spermatozoa are not only relatively but absolutely larger than those of any other animals. In one species which, when adult, is no more than 1/32 in. in length the spermatozoa are about ¼ in. long.

Most species live on or near the bottom, creeping among weeds or burrowing in mud, but some marine species are planktonic. One of the latter, *Gigantocypris,* is the largest member of the group, reaching a length of .9 in., but most species are much smaller and some do not exceed .02 in. in length.

Numerous fossil Ostracoda have been described from the oldest to the most recent formations but the affinities of many are obscure. The recent Ostracoda are generally grouped in two orders. The Myodocopa are exclusively marine and can usually be recognized by the presence of a notch in the margin of the shell near the anterior end. They generally have paired compound eyes and a heart. The Podocopa include both marine and freshwater species. There is no notch in the shell, no paired eyes and no heart.

(W. T. C.; X.)

OSTRACODERMS, a name given collectively to several groups of small fishlike Palaeozoic vertebrates, particularly abundant in the late Silurian and early Devonian formations of Europe and North America. Jaws were not developed, and paired appendages were often absent. These are primitive characteristics which show that they were allied to the living Cyclostomata (*q.v.*), with which they are often grouped to form the vertebrate class Agnatha. All carried bony armour, and internal ossifications are sometimes present as well. The Devonian Antiarchi (Asterolepida), sometimes considered as ostracoderms, are, however, jaw-bearing vertebrates (*see* SELACHIANS).

OSTRAU: *see* MORAVSKÁ OSTRAVA and SLEZSKÁ OSTRAVA.

OSTRICH, the largest living bird; the male may be nearly 8 ft. high, and weigh 300 lb. The ostrich forms the type of the sub-class Ratitae, characterized by the absence of a keel on the breast-bone (*see* ORNITHOLOGY). The genus *Struthio* is unique in possessing only two toes, thus distinguishing it from *Rhea* (*q.v.*), the South American ostrich, which has three toes.

The ostrich, in a wild state, is much less abundant now than formerly. It inhabits sandy plains and open country in Arabia and Africa, the latter more abundantly. It occurs in small troops of five or six, of which one is a cock and the rest hens. At other times it will form mixed herds with zebras and various antelopes. Extremely fleet of foot, when brought to bay the ostrich uses its strong legs as weapons with great effect. Several hens combine to lay their eggs in one nest, and on these the cock sits by night while the females relieve one another by day, though this is more to guard the eggs from beasts of prey than to incubate them, the heat of the sun sufficing for that. The parents display great solicitude for their young. The great value of ostrich feathers, combined with the growing scarcity of the birds themselves, has led to the establishment of ostrich farms, where the birds are kept and deprived of their plumes at regular intervals. Ostrich farming is carried on in Cape Colony, Egypt, Algeria, the French Riviera, southern U.S. and elsewhere. There appear to be four existing species: *S. camlus* of North Africa and Arabia, and *S. australis* of South Africa being the best known.

OSTRICH (STRUTHIO CAMELUS), THE LARGEST OF LIVING BIRDS

OSTROG, a town of Poland, in the province of Volhynia, on the Vilya river. It is an episcopal see of the Orthodox Greek Church, and in the 16th century had a classical academy, converted later into a Jesuit college. Here was made and printed in 1581 the first translation of the Bible into old Slav. In the town is a brotherhood of Cyril and Methodius, which maintains schools of its own. Industries include tanning, potteries, oil-works, soap, candle and tobacco factories. After being plundered by the Cossack chieftain Ghmielnicki in 1648, and later conquered by the Russians, the town fell into decay. Polish after 1918, it was taken by the Russians in 1939 and the Germans in 1941.

OSTROGOTHS or **EAST GOTHS,** one of the two main branches into which the Goths were divided, the other being the Visigoths, or West Goths. *See* GOTHS.

OSTROVSKY, ALEXANDER NIKOLAEVICH (1823–1886), Russian dramatic author, was born on April 12, 1823 in Moscow, where his father was an official of the senate. He studied law in the university of that city, which he quitted without having submitted to the final examination. He was then employed as a clerk in the office of the "Court of Conscience," and subsequently in that of the Commercial Court at Moscow. Among his early comedies are *Byednaya Nivesta* ("The Poor Bride"), *Byednost ne Porok* ("Poverty not a Vice"), and *Ne v'svoi sani ne sadis* (literally "Don't put yourself in another's sledge"). Of this last Nicholas I. said, "it was not a play, but a lesson." The Moscow merchants are strikingly portrayed in *Grozá* (1860, Eng. trans. *The Storm,* by C. Garnett, 1898) the most famous of all his plays, and *Svoyi lyudi sotchtyomsya* ("Between near relatives no accounts are needed") (1850) which was originally called "The Bankrupt." *The Bankrupt* was prohibited for ten years, until the accession of Alexander II., and Ostrovsky was dismissed from the government service and placed under the supervision of the police. The Liberal tendencies of the new reign, however, soon brought relief; Ostrovsky was one of several well-known literary men who were sent into the provinces to report on the condition of the people. Ostrovsky's field of inquiry lay along the upper Volga. This mission inspired several historical dramas, such as *Kuzma Zakharich Minin Soukhorouk, Vassilisa Melentieva* and others. Four of his *Plays* have been translated into English by G. R. Noyes (1917). Ostrovsky enjoyed the patronage of Alexander III., and received a pension of 3,000 roubles a year. With the help of Moscow capitalists he established in that city a model theatre and school of dramatic art, of which he became the first director. He also founded the Society of Russian Dramatic Art and Opera

Composers. He died on June 24, 1886.

OSTUNI, a picturesque walled city of Apulia, Italy, province of Brindisi, 23 mi. N.W. of Brindisi. Pop. (1936) 21,826 (town); 28,247 (commune). It has a 15th century cathedral.

OSTWALD, WILHELM (1853–1932), German chemist, was born at Riga, Livonia, Sept. 2, 1853, and educated at the University of Dorpat (Estonia). In 1881 he became professor in Riga, and six years later was appointed professor of physical chemistry in the University of Leipzig, where he was later director of the Physico-chemical institute. In 1906 he resigned his university appointment and subsequently lived in retirement in Saxony. Ostwald may be regarded as one of the pioneers of modern physical chemistry and with J. H. van't Hoff (*q.v.*) in 1887 he founded the important *Zeitschrift für physikalische Chemie.* His own contributions to the science were mainly in the fields of electrochemistry and solutions.

On the technical side he is remembered chiefly for his discovery in 1900 of a method of oxidizing ammonia to form oxides of nitrogen, a mixture of air and ammonia being passed over a platinum catalyst. By means of this process and by later developments in connection with it, Germany was able to continue the manufacture of explosives during World War I after the Allied blockade had been enforced; the method came to be used in various countries, under the name of the Ostwald-Brauer process, for the manufacture of nitric acid from ammonia. In 1909 Ostwald was awarded the Nobel prize for chemistry.

His published works include *Lehrbuch der allgemeinen Chemie,* 3rd ed. (1910–11), *Grundlinien der anorganischen Chemie,* 5th ed. (1922) and *Die wissenschaftlichen Grundlagen der analytischen Chemie,* 7th ed. (1920), which have been translated into English. His autobiography, *Lebenslinien, eine Selbstbiographie* (3 vols.), appeared in 1926–27. His interests were by no means confined to chemistry, as evidenced by his *Vorlesungen über Naturphilosophie,* 3rd ed. (1905), his numerous studies of colour theory, monism, the technique of painting, etc. His studies of the lives of scientists are notable for their insight into the factors that make for great men (*see* especially his *Grosse Männer*). He died at his country home near Leipzig on April 4, 1932.

See F. G. Donnan, "Ostwald Memorial Lecture," *Journal of the Chemical Society,* 136:316 (London, 1933). (R. E. O.)

OSUNA, a town of southern Spain, in the province of Seville; 57 mi. by rail E.S.E. of Seville. Pop. (1940) 19,552 (mun., 24,083). Osuna is built on a hill, overlooking the fertile plain watered by the Salado, a subtributary of the Guadalquivir. Osuna, the Urso of Hirtius, famous in the 1st century B.C. for its long resistance to the troops of Caesar, and its fidelity to the Pompeians, was subsequently called by the Romans Orsona and Gemina Urbanorum, the last name being due, it is said, to the presence of two urban legions here. Osuna was taken from the Moors in 1239, and given by Alphonso X to the knights of Calatrava in 1264. Don Pedro Giron appropriated it to himself in 1445. One of his descendants, Don Pedro Tellez, was the first holder of the title duke of Osuna, conferred on him by Philip II in 1562. The University of Osuna, founded in 1549, was suppressed in 1820. The industries are agriculture and the making of esparto mats, pottery, bricks, oil, soap, cloth, linen and hats.

OSWALD (d. 992), archbishop of York, was a nephew of Oda, archbishop of Canterbury, and at an early age became, by purchase, head of the Old Minster at Winchester. Desiring to become a monk, he went with Oda's approval to the monastery of Fleury on the Loire—at that time the great centre of reviving Benedictinism. Here he soon distinguished himself by the monastic austerity of his life. In 959 he returned to England at the request of Oda, who, however, died before his arrival. He now went to York to his kinsman the Archbishop Oskytel, who took him with him on a pilgrimage to Rome. Soon after his return he was appointed bishop of Worcester at the recommendation of Dunstan, his predecessor in the see (961). As bishop he took a prominent part in that revival of monastic discipline on Benedictine lines of which Aethelwold, bishop of Winchester, was the most ardent leader. Among other religious houses he founded that of Ramsey in conjunction with Aethelwine, Ealdorman of East Anglia. In 972 he was translated (again at Dunstan's recommendation) to the archbishopric of York, with which he continued to hold the see of Worcester. He died on Feb. 29, 992.

See *Memorials of St. Dunstan,* ed. by W. Stubbs, Rolls series (1874); and T. Raine, *Historians of the Church of York* (1879–86).

OSWALD (*c.* 605–642), king of Northumbria, was one of the sons of Aethelfrith and was expelled from Northumbria on the accession of Edwin, though he himself was a son of Edwin's sister Acha. He appears to have spent some of his exile in Iona, where he was instructed in the principles of Christianity. In 634 he defeated and slew the British king Ceadwalla at a place called by Bede Denisesburn, near Hefenfelth, which has been identified with St. Oswald's Cocklaw, near Chollerford, Northumberland. By this he avenged his brother Eanfrith, who had succeeded Edwin in Bernicia, and became king of Northumbria. Oswald reunited Deira and Bernicia, and soon raised his kingdom to a position equal to that which it had occupied in the time of Edwin, with whom he is classed by Bede as one of the seven great Anglo-Saxon kings. His close alliance with the Celtic church is the characteristic feature of his reign. In 635 he sent to the elders of the Scots for a bishop. On the arrival of Aidan in answer to this request he assigned to him the island of Lindisfarne as his see, near the royal city of Bamborough. He also completed the minster of St. Peter at York which had been begun by Paulinus under Edwin. Bede declares that Oswald ruled over "all the peoples and provinces of Britain, which includes four languages, those of the Britons, Picts, Scots and Angles." His relationship to Edwin may have helped him to consolidate Deira and Bernicia. Early in his reign he was sponsor to the West Saxon king Cynegils, whose daughter he married. In 642 he was defeated and slain at a place called Maserfeld, probably Oswestry in Shropshire, by Penda of Mercia.

See Bede, *Historia Ecclesiastica,* ed. by C. Plummer (1896), ii, 5, 14, 20; iii, 2, 3, 5, 6, 7, 9–14; *Anglo-Saxon Chronicle,* ed. by J. Earle and C. Plummer (1899), *s.a.,* 617, 634, 635, 642, 654.

OSWALDTWISTLE, urban district, Accrington parliamentary borough, Lancashire, England, on Leeds and Liverpool canal; and the London Midland Region route (Church and Oswaldtwistle station). Pop. (1938) 12,620. Area, 7.6 sq.mi. It possesses cotton mills, printworks, bleachworks and chemical works, and in the neighbourhood are collieries, stone quarries and potteries.

OSWEGO, a city of New York, U.S.A., the county seat of Oswego county; on Lake Ontario, 35 mi. N.N.W. of Syracuse, at the mouth of the Oswego river and the Oswego canal, which connects with the State Barge canal at Three River Point, 25 mi. S.E. It is on federal highway 104 and is served by the Lackawanna, the New York Central and the New York, Ontario and Western railways, lake steamers and canal barges. The population was 22,611 in 1950 and 22,062 in 1940 by the federal census. The city has a fine harbour, water power, large hydro- and steam-electric developments. Water-borne commerce consists largely of coal, petroleum products, sand and gravel, raw sugar and grain.

Among the manufactures are textiles, paper containers, matches, candy, boilers and children's shoes. Oswego is the seat of a state normal school (established by the city in 1861 and taken over by the state in 1867). Ft. Ontario (within the city limits) is the oldest fort in North America which is still garrisoned. The site of Oswego was visited by Champlain in 1616. Later it became a station for the Jesuit missionaries and the *coureurs des bois.*

An English trading post was established in 1722, and in 1727 Gov. William Burnet of New York built the first fort. It was an important base of operations during King George's War and the French and Indian War. In 1755–56 the British erected two new forts (Oswego and Ontario) on either side of the mouth of the river, both of which were taken by Montcalm (Aug. 14–15, 1756) and dismantled. The British restored Ft. Ontario in 1759 and kept it garrisoned until they turned it over to the United States in 1796. It was here that Pontiac in 1766 made his acknowledgment to Sir William Johnson of Great Britain's authority. On May 6, 1814, the fort was captured by the British and Canadians, and was held by them for a short time. It was rebuilt and garrisoned by the United States in 1839, abandoned in 1899, and again reconstructed and garrisoned in 1905. Oswego became the county seat in 1816, was incorporated as a village in 1828 (when the canal was completed) and as a city in 1848.

OSWEGO CANAL: *see* New York State Barge Canal System.

OSWEGO TEA (*Monarda didyma*), a North American plant of the mint family (Labiatae), called also American beebalm, native to moist soil from Quebec to Michigan and southward to North Carolina and Georgia. It is a stout perennial, 2 to 3 ft. high, with opposite, lance-shaped, sharply toothed leaves, and showy scarlet flowers, about 2 in. long, borne in dense bracted heads terminating the branches. The Oswego tea, so named because of former medicinal use, is one of the most handsome flowering plants native to eastern North America; several choice varieties are cultivated.

OSWESTRY, municipal borough in the Oswestry parliamentary division of Shropshire, England, near the Welsh border in the N.W. corner of the county. Pop. (est. 1938) 9,726. Area, 3.4 sq.mi. The town is placed where valleys open from the Berwyn mountains, and is a market town between hill and plain as well as a route centre. There are various accounts of the early history of the settlement (*Trer Cadeirau*). The present name comes from Oswald's Tree (alternative Oswald's Cross, Welsh *Croes Oswallt*) and is said to refer to the death of Oswald, king of Northumbria, in a battle fought here against Penda, the ruler of Mercia. The heavily fortified encampment of "Old Oswestry," about a mile from the town, suggests early border warfare. The town was twice burned by Welsh invaders in the middle ages. In the Domesday Survey it is included in the manor of Maesbury. Richard II, by a charter dated 1398, granted all the privileges which belonged to Shrewsbury. In 1582 Elizabeth incorporated the town; her charter was confirmed by James I, 1616.

In the 15th and 16th centuries a weekly market was held at Oswestry for the sale of woollen goods manufactured in the adjoining parts of Wales, but the drapers of Shrewsbury, a rival centre, ruined the trade by refusing to buy cloth there. In 1642 it was garrisoned for Charles I, but two years later surrendered to the parliamentary forces. The church of St. Oswald, originally conventual, is Early English and Decorated, but has been much restored. The grammar school, founded in the reign of Henry IV, occupies modern buildings. During World War I Oswestry benefited greatly by the presence of thousands of troops at Park Hall camp. The Cambrian railway had its headquarters in the town but the engine and carriage works were in part removed by the G.W.R. after 1922. The chief industries are malting, tanning, currying, fellmongery and wool stapling.

OTHMAN (*c.* 574–656), in full Othmān ibn 'Affān, the third of the Mohammedan caliphs, a kinsman and son-in-law of Mohammed and cousin of Abu Sofiān, whose son Moawiya became the first of the Omayyad dynasty. He was elected caliph in succession to Omar in 644, but owing to his weakness and cruelty and his preference of the Koreish for all responsible positions irrespective of their capacity, he produced strife throughout the empire which led to his assassination by Mohammed, son of Abu Bekr. He was succeeded by Ali. *See* Caliphate.

OTHO, MARCUS SALVIUS (a.d. 32–69), Roman emperor, was born on April 28, a.d. 32. He appears first as one of the wildest of Nero's court. In 58 he refused to divorce his wife Poppaea Sabina at Nero's bidding, and was thereupon sent to be governor of Lusitania, where he remained ten years. In 68 Galba, governor of the neighbouring province of Tarraconensis, rebelled against Nero, and Otho accompanied him to Rome, hoping to succeed him. In Jan. 69 Galba adopted Piso as his successor, and Otho at once organized a revolt of the praetorian guard, and on Jan. 15 had himself proclaimed emperor, murdered Galba and Piso, and was accepted by the Senate. He owed his success partly to Galba's disciplinary measures being unpopular with the guards, partly to the power of the memory of Nero, which he further enlisted by restoring his statues and the officials of his household, and proposing to complete his palace, the Golden House. News soon arrived, however, that the army in Germany had declared for Vitellius. On March 14 he started northwards to prevent the Vitellians entering Italy. In this he failed, but his advance guard successfully defended Placentia against Alienus Caecina, compelling him to retire to Cremona, and he held the line of the Po. Opinions were divided in Otho's camp; he himself wishing to force a decisive battle, others advising him to wait for the arrival of the troops from Dalmatia. Otho prevailed, and the main army crossed the Po to Bedriacum, Otho staying behind with the reserve at Brixellum, on the southern bank. The Othonian forces were defeated outside Cremona, and deserted to the enemy. Otho refused to renew the struggle and committed suicide in his tent on the morning of April 15, 69, and was buried at Brixellum.

See Tacitus, *Histories,* i. 12–50, 71–90, ii. 11–51; *Lives* by Suetonius and Plutarch; Dio Cassius lxiv.; L. Paul, "Kaiser M. Salvius Otho" in *Rhein. Mus.* lvii. (1902); W. A. Spooner's Introd. to his edition (1891) of the *Histories* of Tacitus; B. W. Henderson, *Civil War and Rebellion in the Roman Empire,* a.d. *69–70* (1908).

OTIDAE: *see* Bustard.

OTIS, HARRISON GRAY (1837–1917), American journalist, was born near Marietta, O., on Feb. 10, 1837. He became a printer's apprentice, working in various offices in Illinois, Iowa, Ohio and Kentucky. He served throughout the Civil War, and rose to be lieutenant-colonel He was in the Government printing office at Washington, D.C., 1867–70, and in 1870 moved to California, where he managed the Santa Barbara *Press.* In July 1882 he became connected with the Los Angeles *Daily Times,* obtaining control of that paper in 1886. He served in the war with Spain as brigadier-general in the Philippines 1898–99. In 1910 the *Times* building was dynamited, 21 employees being killed. He died at Los Angeles on July 30, 1917.

OTIS, JAMES (1725–1783), American patriot, was born at West Barnstable, Mass., on Feb. 5, 1725. He was the eldest son of James Otis (1702–1778), fourth in descent from John Otis (1581–1657), a native of Barnstaple, Devon, and one of the first settlers (in 1635) of Hingham, Mass. The elder James Otis was elected to the provincial general court in 1758, was its speaker in 1760–1762, and was chief justice of the court of common pleas from 1764 until 1776; he was a prominent patriot in the colony of Massachusetts. The son graduated at Harvard in 1743; and after studying law in the office of Jeremiah Gridley (1702–1767), a well-known lawyer with Whig sympathies, rose to great distinction at the bar, practising first at Plymouth and after 1750 at Boston. In 1760 he published *Rudiments of Latin Prosody,* a book of authority in its time. Soon after the accession of George III. to the throne of England in 1760, the British Government decided upon a rigid enforcement of the navigation acts, which had long been disregarded by the colonists and had been almost wholly evaded during the French and Indian War. The writs of assistance issued in 1755 were about to expire, and it was decided to issue new ones, which would empower custom house officers to search any house for smuggled goods, though neither the house nor the goods had to be specifically mentioned in the writs. Much opposition was aroused in Massachusetts, the legality of the writs was questioned, and the superior court consented to hear argument. Otis held the office of advocate-general at the time, and it was his duty to appear on behalf of the Government. He refused, resigned his office, and appeared for the people against the issue of the writs. The case was argued in the old town house of Boston in Feb. 1761, and the chief speech was made by Otis. His plea was fervid in its eloquence and fearless in its assertion of the rights of the colonists. Going beyond the question at issue, he dealt with the more fundamental question of the relation between the English in America and the home Government, and argued that even if authorized by act of parliament such writs were null and void. The young orator was elected in May of the same year a representative from Boston to the Massachusetts general court. To that position he was re-elected nearly every year of the remaining active years of his life, serving there with his father. In 1766 he was chosen speaker of the house of representatives, but the choice was negatived.

In Sept. 1762 the younger Otis published *A Vindication of the Conduct of the House of Representatives of the Province of Massachusetts Bay,* in defence of the action of that body in sending to the governor a message (drafted by Otis) rebuking him for asking the assembly to pay for ships he had (with authorization of the council and not of the representatives) sent to protect New England fisheries against French privateers; according to this

message "it would be of little consequence to the people whether they were subject to George or Louis, the king of Great Britain or the French king, if both were as arbitrary as both would be if both could levy taxes without parliament." He also wrote various State papers addressed to the colonies to enlist them in the common cause, or sent to the Government in England to uphold the rights or set forth the grievances of the colonists. His influence at home in controlling and directing the movement of events which led to the War of Independence was universally felt and acknowledged; and abroad no American was so frequently quoted, denounced or applauded in parliament and the English press before 1769 as the recognized head and chief of the rebellious spirit of the New England colonists. In 1765 Massachusetts sent him as one of her representatives to the Stamp Act congress at New York, and here he was a conspicuous figure, serving on the committee which prepared the address sent to the British House of Commons. From 1769 almost continually until his death, Otis was harmlessly insane, though he had occasional lucid intervals, serving as a volunteer in the battle of Bunker Hill in 1775 and arguing a case in 1778. He was killed by lightning (it is said that he had often expressed a wish that he might die in this way) at Andover, Mass., on May 23, 1783.

Otis's political writings exercised an enormous influence, his pamphlets being among the most effective presentations of the arguments of the colonists against the arbitrary measures of the British ministry. His more important pamphlets were *A Vindication of the Conduct of the House of Representatives of the Province of Massachusetts Bay* (1762); *The Rights of the British Colonies Asserted and Proved* (1764); *A Vindication of the British Colonies against the Aspersions of the Halifax Gentleman in his Letter to a Rhode Island Friend*—a letter known at the time as the "Halifax Libel" (1765); and *Considerations on Behalf of the Colonists in a Letter to a Noble Lord* (1765).

The best biography is that by William Tudor (Boston, 1823); there is a shorter one by Francis Bowen (Boston, 1847). The best account of Otis's characteristics and influence as a writer may be found in M. C. Tyler's *Literary History of the American Revolution* (1897). Consult the notes on the Writs of Assistance by Horace Gray, Jr., in Quincy's *Massachusetts Reports, 1761–1772* (Boston, 1865). *See* also Francis Wilson Sprague, *Birthplace of the Patriot James Otis* (1917).

OTLEY, an urban district in the Ripon parliamentary division of the West Riding of Yorkshire, England, 10 mi. N.W. of Leeds by road.

The population in 1951 was 11,568. Area 4.6 sq.mi. It stands on the Wharfe at the foot of the precipitous Chevin. Southwest of Otley the Guiseley gap affords a route, only 4 mi. long, between the Aire and the Wharfe which is traversed by roads and railways and brings much of the Aire valley within range of Otley markets.

In 937 Aethelstan granted the manor of Otley to the archbishop of York. The town and the church were laid waste in 1069. Otley became an important local centre of the woollen cloth industry, which was introduced late in the 11th century. An annual fair was granted in 1222 and a weekly market in 1248.

The growth of cereals, which was important until the 18th century, was abandoned in favour of pastoral industries for the supply of meat to the dense population on the Yorkshire coal field. Today the prosperity of Otley depends not on its importance as an agricultural centre but on its industries, chief among which are the manufacture of printing machinery, papermaking and worsted spinning and weaving.

OTOLITH: *see* EQUILIBRIUM, ANIMAL.

OTOMACAN, an independent linguistic stock of South American Indians, named from the Otomacas, its best known tribe. The Otomacas lived in south-western Venezuela, along the Orinoco between the Meta and Arauca rivers. In recent times they have spread westward. Described by early writers as one of the most barbarous tribes of the whole Orinoco region, they appear to have been sedentary agriculturalists, cultivating their fields of manioc and maize communally, the produce, with that from hunting and fishing, being divided among all by the chief. They were noted as clay-eaters, even their bread being mixed with it, and made great use of narcotic snuff. They were monogamous, and it is said that they married all young girls to old widowers, and all young men to elderly widows.

See J. Gumilla, *Histoire naturelle, civile et géographique de l'Orénoque* (Avignon, 1758).

OTOMI, an important group of Indians on the central mesa of Mexico. The ancient territory of the Otomi proper comprised the states of Guanajuato and Querétaro, south-western Hidalgo and northern Mexico, extending to the hills overlooking Mexico valley and city. With them are reckoned, on the basis of related speech, the Pame of eastern San Luis Potosi and the Mazahua and Pirinda of western Mexico (state). The Otomian languages are tonal and built up from monosyllabic elements. This analogy to Chinese has led to theories of relationship, generally fantastic. Remote kinship with the Zapotecan group is, however, possible. The Otomi passed as dull boors among the Aztec; they were provincially backward as compared with centres of native culture like Mexico, Tezcoco, Cholula, and possessed no large towns. The nearer ones were all subject to the Aztec. To-day they are peaceful and number about a quarter of a million.

OTRANTO, seaport and archiepiscopal see, Apulia, Italy, in province of Lecce, 29½ mi. S.E. from it by rail, 49 ft. above sea-level. Pop. (1951) 3,400 (commune). It is on the E. coast of the peninsula of ancient Calabria (*q.v.*). The castle was erected by Alfonso of Aragon; the cathedral, consecrated in 1088, has a rose window and side portal of 1481. The interior, a basilica with nave and two aisles, contains a mosaic pavement of 1165. It has a crypt supported by 42 marble columns. The church of S. Pietro has Byzantine frescoes.

Otranto occupies the site of the ancient Hydrus or Hydruntum, a town of Greek origin. In Roman times it was less important than Brundisium as a point of embarkation for the East. It was taken by Robert Guiscard in 1068. In 1480 it was utterly destroyed by the Turkish fleet, and has never since recovered its importance. About 30 mi. S.E. lies the promontory of S. Maria di Leuca (so called since ancient times from its white cliffs), the southeast extremity of Italy, the ancient Promontorium Iapygium or Sallentinum. The district between this promontory and Otranto is thickly populated, and very fertile. It was a supply base in World Wars I and II. The straits are about 40 mi. wide; cables leave here for Valona and Corfu.

OTTAKAR I. (d. 1230), king of Bohemia, was a younger son of King Vladislav II. (d. 1174) and a member of the Premyslide family, hence he is often referred to as Premysl Ottakar I. Recognized as ruler of Bohemia by the emperor Henry VI. in 1192, he was, however, soon overthrown, but in 1196 forced his brother, King Vladislav III., to abandon Bohemia to him and to content himself with Moravia. Ottakar first sought the support of the German king Philip, duke of Swabia, but then went over to his rival Otto of Brunswick. Philip thereupon invaded Bohemia, and Ottakar changed sides once more. Later still, he supported the young king, Frederick II. He united Moravia with Bohemia in 1222, and when he died in 1230 he left to his son, Wenceslaus I., a kingdom united and comparatively peaceable.

OTTAKAR II., or PREMYSL OTTAKAR II. (*c.* 1230–1278), king of Bohemia, was son of King Wenceslaus I.; his maternal grandfather was the German king, Philip, duke of Swabia. In his father's lifetime he ruled Moravia, and in 1251 secured his election as duke of Austria, where he strengthened his position by marrying (Feb. 11, 1252) Margaret (d. 1267), sister of Duke Frederick II., the last of the Babenbergs and widow of the German king, Henry VII. In Sept. 1253 he succeeded his father in Bohemia, and in 1254 concluded peace with Bela IV. of Hungary, who had claimed Styria, advancing the Austrian frontier to the present line. In 1259 he expelled the Hungarians from the rest of Styria, then divorced his wife, married a granddaughter of Bela IV. and secured his investiture (by letter) with Austria and Styria from the German king, Richard Cornwallis.

In 1269 Ottakar II. inherited Carinthia and part of Carniola; and having made good his claim, contested by the Hungarians, in battle, he was the most powerful prince in Germany when an election for the German throne took place in 1273. The electors, however, fearing his power, chose Rudolph of Habsburg, who in 1276 placed Ottakar under the ban, besieged Vienna, and com-

pelled Ottakar to renounce all his possessions except Bohemia and Moravia. (*See* AUSTRIA, EMPIRE OF.) Ottakar was killed at Dürnkrut on the March, Aug. 26, 1278, in an attempt to recover his lands. Clever, strong and handsome, he is a famous figure both in history and in legend, and is the subject of a tragedy by F. Grillparzer, *König Ottokars Glück und Ende.*

See O. Lorenz, *Geschichte, König Ottokars,* ii (Vienna, 1866); F. Palacky, *Geschichte von Böhmen,* vol. i (Prague, 1844).

OTTAVA RIMA, a stanza of eight iambic lines, containing three rhymes, invariably arranged as follows:—*a b a b a b c c.* It is an Italian invention of the 14th century. Giovanni Boccaccio employed it for the *Teseide* (1340) and for the *Filostrato* (about seven years later). These epics gave to ottava rima its classic character. In the succeeding century it was employed by Politian and by Matteo Boiardo for his famous *Orlando Innamorato* (1486). It was Luigi Pulci, however, in the *Morgante Maggiore* (1482), who invented the peculiar mock-heroic, or rather half-serious, half-burlesque, style with which ottava rima has been most commonly identified. The most striking monument in ottava rima in English is *Don Juan* (1819–24). Byron also employed this measure in *The Vision of Judgment* (1822). Meanwhile, Shelley also became attracted by it, and in 1820 translated the *Hymns* of Homer into ottava rima. In the peninsula the form was largely used; *e.g.,* by Juan Boscán Almogaver (1490?–1542), by Alonso de Ercilla y Zúñiga (1533–94) in *La Araucana,* by Luis de Camoens in *Os Lusiadas* (1572) and by Lope de Vega Carpio.

OTTAWA, a city of Carleton county, province of Ontario, and the capital of Canada, on the south bank of the Ottawa river, 101 mi. W. of Montreal and 217 mi. N.E. of Toronto. Pop. (1951) 198,773; greater Ottawa 278,078, including the city of Hull (43,204) and various suburbs.

The city stands for the most part on a cluster of hills, 60 to 155 ft. above the river. It is on the transcontinental lines of both the Canadian National and Canadian Pacific railways, and has direct communication by both systems to Montreal, Toronto and other points in Canada, as well as by the New York Central to New York and elsewhere in the United States.

The site of the city is picturesque. For three miles it follows the high southern bank of the Ottawa from the Chaudière falls, whose mist-crowned cauldron is clearly visible from the summit of Parliament hill, to and beyond the Rideau falls, so named by early French explorers because of their curtainlike appearance. The Rideau, a southern tributary of the Ottawa, once formed the eastern boundary of the city, which, however, in 1950 absorbed a string of suburbs that lie along its eastern banks. The Rideau canal cuts the city in two, the western portion being known as Upper Town and the eastern as Lower Town. For many years the canal divided the two sections of the population, the English occupying Upper Town and the French Lower Town, but a trend toward city-wide population homogeneity began during the World War II years.

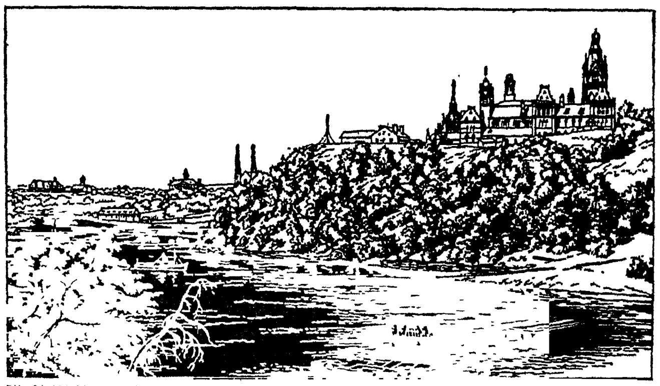
Opposite and a little below the mouth of the Rideau river, the Gatineau flows into the Ottawa from the north. The Ottawa is the scene of large hydroelectric developments, and is an active pulpwood artery for the paper mills in the Hull-Ottawa area. Above the Chaudière falls the river is broken by the Deschenes rapids, and beyond these again it expands into Lake Deschenes. To the north are the Laurentian hills, broken by the picturesque Gatineau valley.

Buildings.—The crowning architectural feature of the city is the splendid group of Gothic buildings on the summit of Parliament hill. The three blocks are on the sides of a great quadrangle, the fourth side being historic Wellington street. The cornerstone of the main building was laid by the prince of Wales in 1860. With the exception of the library, it was destroyed by fire in 1916, and was later rebuilt. It contains the house of commons and the senate chambers. In the 300-ft. tower is a remarkably beautiful war memorial chamber, and above it is hung a carillon of 53 bells. The Langevin block on Wellington across the street from the parliament buildings is used for departmental purposes, and, to meet the increasing needs of the government, a group of wooden buildings was erected on the banks of the Ottawa, west of Parliament hill. Other national institutions with impressive buildings scattered throughout the city are the public archives, royal mint, National Research council, National museum and National Art gallery and Dominion observatory. Other buildings are the public library, University of Ottawa, the collegiate institutes, Normal and Model school, St. Patrick's college, Carleton college and the Roman Catholic and Church of England cathedrals. City charities include a large civic hospital and nurses' home, a general hospital supported by the Roman Catholics and three special hospitals devoted to contagious diseases.

A system of public parks and driveways, partly within and partly without the city, adds very largely to its attractions. These were built and are maintained by the federal district commission. Statues of Queen Victoria, as well as of Sir John Macdonald, Sir Wilfrid Laurier and other Canadian statesmen, stand on Parliament hill. A memorial was erected on Connaught circle, below Parliament hill, in honour of those killed in World War I. Rideau hall, official residence of the governor general, lies on the eastern boundary of the city at the entrance to Rockcliffe park.

History.—The earliest description of the site of Ottawa is that of Samuel de Champlain, in his *Voyages.* In June 1613, on his way up the river, he came to a tributary on the south side, "at the mouth of which is a marvellous fall. For it descends a height of twenty or twenty-five fathoms with such impetuosity that it makes an arch nearly four hundred paces broad. The savages take pleasure in passing under it, not wetting themselves, except from the spray that is thrown off." This was the Rideau falls, but a good deal of allowance must be made for exaggeration in Champlain's account. Continuing up the river, "we passed," he says, "a fall, a league from there, which is half a league broad and has a descent of six or seven fathoms. There are many little islands. The water falls in one place with such force upon a rock that it has hollowed out in course of time a large and deep basin, in which the water has a circular motion and forms large eddies in the middle, so that the savages call it *Asticou,* which signifies boiler. This cataract produces such a noise in this basin that it is heard for more than two leagues." The present name, Chaudière, is the French equivalent of the old Indian name.

For two hundred years and more after Champlain's first visit the Chaudière portage was the main thoroughfare from Montreal



BY COURTESY OF THE CANADIAN NATIONAL RAILWAYS

BARRACK HILL, IN OTTAWA, WITH A PART OF THE PARLIAMENTARY BUILDINGS IN THEIR ORIGINAL STATE. FROM AN OLD PRINT

to the great western fur country; but it was not until 1800 that any permanent settlement was made in the vicinity. In that year Philemon Wright, of Woburn, Mass., built a home for himself at the foot of the portage, on the Quebec side of the river, where the city of Hull now stands; but for some time the precipitous cliffs on the south side seem to have discouraged settlement there. Finally about 1820 one Nicholas Sparks moved over the river and cleared a farm in what is now the heart of Ottawa. Seven years later Col. John By, R.E., was sent out to build a canal from a point below the Chaudière falls to Kingston on Lake Ontario. The canal, completed at a cost of $2,500,000, was never of any great commercial importance; it was never called upon to fulfil its primary object, as a military work to enable gunboats and military supplies to reach the lakes from

Montreal without being exposed to attack along the St. Lawrence frontier. The building of the canal created a fair-sized settlement at its Ottawa end, which came to be known as Bytown. As the lumber trade developed Bytown rapidly increased in wealth and importance. In 1854 it was incorporated as a city, the name being changed to Ottawa; and four years later Queen Victoria selected Ottawa as the capital of the province of Canada. Ottawa was admirably situated for a capital from a political and military point of view; but there is reason to believe that the deciding factor was the pressure exerted by the four other rival claimants, Montreal, Quebec, Toronto and Kingston, any three of which would have fiercely resented the selection of the fourth. The first session of parliament in Ottawa was opened in 1865. The British North America act of 1867 made Ottawa the capital of Canada.

OTTAWA, a city of Illinois, U.S., 84 mi. S.W. of Chicago, at the confluence of the Illinois and the Fox rivers; the county seat of Lasalle county. It is on the Illinois and Michigan canal and the Illinois waterway, and is served by the Burlington Route and the Rock Island railway. Population in 1950, 16,957.

The city's manufactures (including plate glass, building tile, firebrick and agricultural implements) had a value of more than $20,000,000 in 1950. The mouth of the Fox river was visited early by the French explorers, and Father Louis Hennepin discovered coal there in 1680. On Starved Rock (8 mi. W., on the south bank of the Illinois, in a state park of 900 ac.) Robert de la Salle in 1683 built Fort St. Louis, which was used by fur traders as late as 1718, and in 1770 was the last refuge of a band of Illini, pursued by the Potawatomis and besieged there until they died of starvation. Ottawa was laid out in 1831, incorporated in 1837 and chartered as a city in 1853. On Aug. 21, 1858, it was the scene of the first of the Lincoln-Douglas debates.

OTTAWA, a city of Kansas, U.S., 58 mi. S.W. of Kansas City, on the Marais des Cygnes (or Osage) river, at an altitude of 926 ft.; the county seat of Franklin county. It is on federal highways 50S and 59 and is served by the Missouri Pacific and the Santa Fe railways. Pop. (1950) 10,081 by federal census; (1940) 10,193. Ottawa has a large trade in poultry and dairy products, fruit and other farm produce. Its manufacturing establishments include creameries, flour mills, poultry-packing plants and factories making steel products and chicken coops. It is the seat of Ottawa university (Baptist), established in 1865. Ottawa was in the reservation of the Ottawa Indians until they were moved (1865) to the Indian territory. A mission was established there in 1839. The city was chartered in 1866.

OTTAWA, the largest tributary of the river St. Lawrence; ranking ninth in length among the rivers of Canada, being 696 mi. long. It flows first westward to Lake Timiskaming; thence southeast and east. The principal tributaries on the left bank are the Rouge (115 mi.), North Nation (60), Lièvre (205), Gatineau (240), Coulonge (135), Dumoine (80); and on the right bank, the South Nation (90), Mississippi (105), Madawaska (130) and Petawawa (95). Canals at Ste. Anne, Carillon and Grenville (begun 1825 and completed 1843 to 6 ft.; deepened to 9 ft. by 1886) permit the passage of vessels from Montreal up to the city of Ottawa. At Ottawa the river is connected with Lake Ontario by the Rideau canal. The Ottawa above Chaudière falls at Ottawa city is used only for floating pulpwood logs and for generating electricity. Above Lake Timiskaming there are four major dams for storage reservoirs having a total drainage area of 28,900 sq.mi.; below Timiskaming there are large power developments at La Cave, Des Joachims, Bryson, Chenaux, Chats and Chaudière, generating more than 1,000,000 h.p.

The Ottawa was first explored by Samuel de Champlain in 1613. Champlain describes many of its tributaries, the Chaudière and Rideau falls, the Long Sault, Chats and other rapids, as well as the character of the river and its banks, with minuteness and reasonable accuracy. The Long Sault rapids on the Ottawa, opposite the Grenville canal and about midway between Montreal and the capital, were the scene of one of the noblest exploits in Canadian history, when in 1661 the young sieur des Ormeaux with 16 comrades and a handful of Indian allies deliberately gave their lives to save New France from an invasion of the Iroquois. They intercepted the war party at the Long Sault, and for nearly a week held them at bay. When finally the last Frenchman fell under a shower of arrows, the Iroquois were thoroughly disheartened and returned crestfallen to their own country. For 150 years thereafter the Ottawa was the great canoe highway from Montreal to the west for explorers and fur traders. Throughout the 19th century the Ottawa was the thoroughfare of lumbermen, whose immense rafts went from its upper waters to Montreal and Quebec. Bustling steamboat transportation of the 1886–1914 period finally succumbed to automobile competition, and the river and canals thereafter were used only by pleasure crafts.

OTTER, the name of an aquatic carnivore inhabiting Europe and Asia. The otter (*Lutra lutra*) has an elongated body, short limbs terminating in broad webbed feet, the toes of which are armed with claws, a broad, flat head and a tail about half the length of the body. The muzzle is broad, the whiskers thick, the eyes small and the ears short and rounded. The fur consists of a short, soft, gray underfur, interspersed with longer, stiffer hairs, the points of which are bright brown. The average length is about 3½ ft., the weight of a male 18 to 24 lb., the female being about 4 lb. less. The otter lives on fish and inhabits streams, rivers, lakes and, in some localities, the sea. The female produces one to three young in March or April, bringing them up in a nest of grass in a hollow in a riverbank or under the roots of an overhanging tree. Otter hunting, with packs of special hounds, is a pastime in parts of England.

In North America, *L. lutra* is replaced by the larger *L. canadensis;* and other species with similar habits are found in South America, Africa and southern Asia.

BY COURTESY OF THE N.Y ZOOLOGICAL SOCIETY

OTTERS (LUTRA LUTRA), WIDELY DISTRIBUTED THROUGH EUROPE AND ASIA

The sea otter (*Enhydra lutris*) is confined to the North Pacific. It is larger and more heavily built than the European otter and possesses a very valuable coat of fur, because of which it has been almost exterminated. Sea otters feed on shellfish. Otters form a section of the family Mustelidae (*see* CARNIVORA).

See Elliott Coues, *Monograph of North American Fur-Bearing Animals.*

OTTERY ST. MARY, a market town of Devonshire, Eng., 12 mi. N.E. of Exeter on the Southern Region railway route. Pop. of urban district (1951) 4,015. Area 15.6 sq.mi. The parish church is Early English, with Decorated and Perpendicular additions. It has transeptal towers, imitated from Exeter cathedral. The manor of Ottery belonged to the abbey of Rouen in the time of Edward the Confessor. The church was dedicated in 1260 by Walter Bronescombe, bishop of Exeter, and enlarged by Bishop John Grandisson, *c.* 1335. The town has a large agricultural trade, and Honiton lace is a home industry. It was the birthplace of S. T. Coleridge.

OTTO I (912–973), THE GREAT, Roman emperor, eldest son of King Henry I the Fowler by his second wife Matilda, was born on Nov. 23, 912. Little is known of his early years, but he probably shared in some of his father's campaigns. In 929 he married Edith, daughter of Edward the Elder, king of the English, and sister of the reigning King Aethelstan. In 936 Otto was chosen German king and crowned by Hildebert, archbishop of Mainz. Otto soon showed his intention of breaking with the policy of his father, who

had been content with a nominal superiority over the duchies; in 937 he punished Eberhard, duke of Franconia, for an alleged infringement of the royal authority; and in 938 deposed Eberhard, duke of Bavaria. Trouble soon arose in Saxony, probably from his refusal to give certain lands to his half-brother, Thankmar, who, although the king's senior, had been passed over in the succession as illegitimate. Thankmar, aided by an influential Saxon noble named Wichmann, and by Eberhard of Franconia, seized the fortress of Eresburg and took Otto's brother Henry prisoner; but soon afterwards he was defeated by the king and killed whilst taking sanctuary. The other conspirators were pardoned, but in 939 a fresh revolt broke out under the leadership of Henry, and Giselbert, duke of Lorraine. Otto gained a victory near Xanten, which was followed by the surrender of the fortresses held by his brother's adherents in Saxony, but the rebels, joined by Eberhard of Franconia and Archbishop Frederick of Mainz, continued the struggle, and Giselbert of Lorraine transferred his allegiance to Louis IV., king of France. Otto's precarious position was saved by a victory near Andernach when Eberhard was killed, and Giselbert drowned in the subsequent flight. Henry took refuge with Louis of France, but was soon restored to favour and entrusted with the duchy of Lorraine, where, however, he was unable to restore order. Otto therefore crossed the Rhine and deprived his brother of authority. Henry then became involved in a plot to murder the king, which was discovered in time, and the good offices of his mother secured him a pardon at Christmas 941.

The deaths of Giselbert of Lorraine and of Eberhard of Franconia, quickly followed by those of two other dukes, enabled Otto to unite the stem-duchies more closely with the royal house. In 944 Lorraine was given to Conrad, surnamed the Red, who in 947 married the king's daughter Liutgard; Franconia was retained by Otto in his own hands; Henry married a daughter of Arnulf, duke of Bavaria, and received that duchy in 947; and Swabia came in 949 to the king's son Ludolf, who had married Ida, a daughter of the late duke, Hermann. During these years the tribes living between the Elbe and the Oder were made tributary, bishoprics were founded in this district, and in 950 the king himself marched against the Bohemians and reduced them to dependence. Strife between Otto and Louis IV. of France had arisen when the French king sought to obtain authority over Lorraine and aided the German rebels in 939; but after the German king had undertaken an expedition into France, peace was made in 942. Afterwards, when Louis became a prisoner in the hands of his powerful vassal Hugh the Great, duke of France, Otto attacked the duke, who, like the king, was his brother-in-law, captured Reims, and negotiated a peace between the two princes; and in subsequent struggles between them his authority was several times invoked.

In 945 Berengar I., margrave of Ivrea, left the court of Otto and returned to Italy, where he soon obtained a mastery over the country. After the death in 950 of Lothair, king of Italy, Berengar sought the hand of his widow Adelaide for his son Adalbert; and Henry of Bavaria and Ludolf of Swabia had already been meddling independently of each other in the affairs of northern Italy. In response to an appeal from Adelaide, Otto crossed the Alps in 951. He assumed the title of king of the Lombards, and having been a widower since 946, married Adelaide and negotiated with Pope Agapetus II. about his reception in Rome. The influence of Alberic, prince and senator of the Romans, prevented the pope returning a favourable answer to the king's request. But when Otto returned to Germany in 952 he was followed by Berengar, who did homage for Italy at Augsburg. The chief advisers of Otto at this time were his wife and his brother Henry. Henry's influence seems to have been resented by Ludolf, who in 946 had been formally designated as his father's successor. When Adelaide bore a son, and a report gained currency that Otto intended to make this child his heir, Ludolf rose in revolt and was joined by Conrad of Lorraine and Frederick of Mainz. Otto fell into the power of the rebels at Mainz and was compelled to agree to demands made by them, which, however, he promptly revoked on his return to Saxony. Ludolf and Conrad were declared deposed, and in 953 war broke out in Lorraine and Swabia, and afterwards in Saxony and Bavaria. Otto was finally victorious and with the capture of Regensburg in 955 the rising ended. Conrad and Ludolf retained their estates, but their duchies were not restored to them. Meanwhile the Magyars had renewed their ravages and were attacking Augsburg. Otto marched against them, and in a battle fought on the Lechfeld Aug. 10, 955, the king's troops gained a victory which freed Germany from these invaders; while in the same year Otto defeated the Slavs ravaging the Saxon frontier.

About this time the king seems to have perceived the necessity of ruling in closer union with the church. Lands and privileges were granted to prelates, additional bishoprics were founded, and some years later Magdeburg was made the seat of an archbishop. In 960 Otto was invited to come to Italy by Pope John XII., who was hard pressed by Berengar, and he began to make preparations for the journey. As Ludolf had died in 957 and Otto, his only son by Adelaide, had been chosen king at Worms, the government was entrusted to Bruno of Cologne, and Archbishop William of Mainz, a natural son of the king. Reaching Pavia at Christmas 961, the king promised to defend and respect the church. He then proceeded to Rome, where he was crowned emperor on Feb. 2, 962. After the ceremony he confirmed the rights and privileges which had been conferred on the papacy, while the Romans promised obedience, and Pope John took an oath of fidelity to the emperor. But as he did not long observe his oath he was deposed at a synod held in St. Peter's, after Otto had compelled the Romans to swear they would elect no pope without the imperial consent; and a nominee of the emperor, who took the name of Leo VIII., was chosen in his stead. A pestilence drove Otto to Germany in 965, and finding the Romans again in arms on his return in 966, he allowed his soldiers to sack the city, and severely punished the leaders of the rebellion. His next move was against the Greeks and Saracens of southern Italy, but seeking to attain his objects by negotiation, sent Liudprand, bishop of Cremona, to the eastern emperor Nicephorus II. to arrange for a marriage treaty between the two empires. Nicephorus refused to admit the validity of Otto's title, and the bishop was roughly repulsed; but the succeeding emperor, John Zimisces, was more reasonable, and Theophano, daughter of the emperor Romanus II., was married to the younger Otto in 972. The same year witnessed the restoration of peace in Italy and the return of the emperor to Germany, where he received the homage of the rulers of Poland, Bohemia and Denmark; but he died suddenly at Memleben on May 7, 973.

The empire was less universal under Otto, its restorer, than Charlemagne, but what it lacked in splendour it gained in stability. His object was not to make the state religious but the church political, and the clergy must first be officials of the king, and secondly members of an ecclesiastical order. He shared the piety and superstition of the age, and did much for the spread of Christianity. Although himself a stranger to letters he welcomed scholars to his court and eagerly seconded the efforts of his brother Bruno to encourage learning; and while he neither feared nor shirked battle, he was always ready to secure his ends by peace.

OTTO II. (955–983), Roman emperor, was the son of the emperor Otto the Great, by his second wife Adelaide. He was chosen German king at Worms in 961 and on Dec. 25, 967, was crowned joint emperor at Rome by Pope John XIII. On

April 14, 972, he married Theophano, daughter of the eastern emperor Romanus II., and after sharing in various campaigns in Italy, returned to Germany and became sole emperor on the death of his father in May 973. After suppressing a rising in Lorraine, difficulties arose in southern Germany, probably owing to Otto's refusal to grant the duchy of Swabia to Henry II., the Quarrelsome, duke of Bavaria. The first conspiracy was easily suppressed, and in 974 an attempt on the part of Harold III., king of the Danes, to throw off the German yoke was also successfully resisted; but an expedition against the Bohemians led by the king in person in 975 was a partial failure owing to the outbreak of further trouble in Bavaria. In 976 Otto deposed Duke Henry, restored order for the second time in Lorraine, and made another expedition into Bohemia in 977, when King Boleslaus II. promised to return to his earlier allegiance. Having crushed an attempt made by Henry to regain Bavaria, Otto was suddenly attacked by Lothair, king of France, who held Aix in his possession for a few days; but when the emperor retaliated by invading France he met with little resistance. He was, however, compelled by sickness among his troops to raise the siege of Paris, and on the return journey the rearguard of his army was destroyed and the baggage seized by the French. An expedition against the Poles was followed by peace with France, when Lothair renounced Lorraine.

The emperor then prepared for a journey to Italy. In Rome, where he restored Pope Benedict VII., he held a splendid court, attended by princes and nobles from all parts of western Europe. He was next required to punish inroads of the Saracens on the Italian mainland, and in September 981 he marched into Apulia, where he met at first with considerable success; but an alliance between the Arabs and the Eastern Empire, whose hostility had been provoked by the invasion of Apulia, resulted in a severe defeat for Otto's troops near Stilo in July 982. Without revealing his identity, the emperor escaped on a Greek vessel to Rossano. At a diet held at Verona, largely attended by German and Italian princes, a fresh campaign was arranged against the Saracens. Proceeding to Rome, Otto secured the election of Peter of Pavia as Pope John XIV. Just as the news reached him of a general rising of the tribes on the eastern frontier of Germany, he died in his palace in Rome on Dec. 7, 983.

OTTO III. (980–1002), Roman emperor, son of the emperor Otto II. and Theophano, daughter of the eastern emperor Romanus II., was born in July 980, chosen as his father's successor at Verona in June 983 and crowned German king at Aix-la-Chapelle on Dec. 25. Otto II. had died a few days before this ceremony, but the news did not reach Germany until after the coronation. Early in 984 the king was seized by Henry II., the Quarrelsome, the deposed duke of Bavaria, who claimed the regency as a member of the reigning house, and probably entertained the idea of obtaining the kingly dignity himself. A strong opposition was quickly aroused, and when Theophano and Adelaide, widow of the emperor Otto the Great, appeared in Germany, Henry was compelled to hand over the young king to his mother. Otto's abilities were carefully cultivated by Bernward, afterwards bishop of Hildesheim, and by Gerbert of Aurillac, archbishop of Reims, and he was called "the wonder of the world." The government of Germany during his minority was in the hands of Theophano, and after her death in June 991 passed to a council in which the chief influence was exercised by Adelaide and Willigis, archbishop of Mainz.

Having accompanied his troops in expeditions against the Bohemians and the Wends, Otto was declared of age in 995. In 996 he crossed the Alps and was recognized as king of the Lombards at Pavia. Before he reached Rome, Pope John XV., who had invited him to Italy, had died, whereupon he raised his own cousin Bruno, son of Otto duke of Carinthia, to the papal chair as Pope Gregory V., and by this pontiff Otto was crowned emperor on May 21, 996. On his return to Germany, the emperor learned that Gregory had been driven from Rome, which was again in the power of John Crescentius, patrician of the Romans, and that a new pope, John XVI., had been elected. Leaving his aunt, Matilda, abbess of Quedlinburg, as regent of Germany, Otto, in Feb. 998, led Gregory back to Rome, took the castle of St. Angelo by storm and put Crescentius to death. A visit to southern Italy, where many of the princes did homage to the emperor, was cut short by the death of the pope, to whose chair Otto then appointed his former tutor Gerbert, who took the name of Sylvester II.

In the palace which he built on the Aventine, Otto sought to surround himself with the splendour and ceremonial of the older emperors of Rome, and dreamed of making Rome once more the centre of a universal empire. Many names and customs were introduced into his court from that of Constantinople; he proposed to restore the Roman senate and consulate, revived the office of patrician, called himself "consul of the Roman senate and people" and issued a seal with the inscription, "restoration of the Roman empire." Passing from pride to humility he added "servant of the apostle," and "servant of Jesus Christ" to the imperial title, spent a fortnight in prayer in the grotto of St. Clement and did penance in various Italian monasteries.

Leaving Italy in the summer preceding the year 1000, when it was popularly believed that the end of the world was to come, Otto made a pilgrimage to the tomb of his old friend Adalbert, bishop of Prague, at Gnesen, and raised the city to the dignity of an archbishopric. He then went to Aix, and opened the tomb of Charlemagne, where, according to a legendary tale, he found the body of the great emperor sitting upright upon a throne, wearing the crown and holding the sceptre.

On his return to Rome, trouble arose between Otto and the citizens, and for three days the emperor was besieged in his palace. After a temporary peace, he fled to the monastery of Classe near Ravenna. Troops were collected, but whilst conducting a campaign against the Romans, Otto died at Paterno near Viterbo on Jan. 23, 1002, and was buried at Aix-la-Chapelle.

OTTO IV. (*c.* 1182–1218), Roman emperor, second son of Henry the Lion, duke of Saxony, and Matilda, daughter of Henry II., king of England, was most probably born at Argenton in central France. His father died when he was still young, and he was educated at the court of his uncle Richard I., king of England, under whose leadership he gained valuable experience in war, being appointed duke of Aquitaine, count of Poitou and earl of Yorkshire. When the emperor Henry VI. died in September 1197, some of the princes under the leadership of Adolph, archbishop of Cologne, were anxious to find a rival to Philip, duke of Swabia, who had been elected German king. After some delay their choice fell upon Otto, who was chosen king at Cologne on June 9, 1198. Hostilities broke out at once, and Otto, after a series of defeats, was driven to Brunswick. Preparations were made to drive him from here, when he was saved by the murder of Philip in June 1208. Many of the supporters of Philip now made overtures to Otto, and an attempt to set up Henry I., duke of Brabant, having failed, Otto submitted to a fresh election and was chosen German king at Frankfort on Nov. 11, 1208, in the presence of a large gathering of princes. A general reconciliation followed, which was assisted by the betrothal of Otto to Philip's eldest daughter Beatrix, but as she was only ten years old, the marriage was deferred until July 22, 1212. The pope, who had previously recognized the victorious Philip, hastened to return to the side of Otto; large concessions were made to the church.

In August 1209 the king set out for Italy. Meeting with no opposition, he was received at Viterbo by Innocent, but refused the papal demand that he should concede to the church all the territories which, previous to 1197, had been in dispute between

the Empire and the Papacy, consenting, however, not to claim supremacy over Sicily. He was crowned emperor at Rome on Oct. 4, 1209, a ceremony which was followed by fighting between the Romans and the German soldiers. The pope then requested the emperor to leave Roman territory; but he remained near Rome for some days, demanding satisfaction for the losses suffered by his troops. The breach with Innocent soon widened, and in violation of the treaty made with the pope Otto attempted to recover for the Empire all the property which Innocent had annexed to the Church, and rewarded his supporters with large estates in the disputed territories.

Having occupied Tuscany he marched into Apulia, part of the kingdom of Frederick of Hohenstaufen, afterwards the emperor Frederick II., and on Nov. 18, 1210, was excommunicated by the pope. Regardless of this sentence Otto completed the conquest of southern Italy, but the efforts of Innocent had succeeded in arousing considerable opposition in Germany, where the rebels were also supported by Philip Augustus, king of France. A number of princes assembled at Nuremberg declared Otto deposed, and invited Frederick to fill the vacant throne. Returning to Germany in March 1212, Otto made some headway against his enemies until the arrival of Frederick towards the close of the year. The death of his wife in August 1212 had weakened his hold on the southern duchies, and he was soon confined to the district of the lower Rhine, although supported by money from his uncle King John of England. The final blow to his fortunes came when he was decisively defeated by the French at Bouvines in July 1214. He escaped with difficulty from the fight and took refuge in Cologne. His former supporters hastened to recognize Frederick; and in 1216 he left Cologne for Brunswick, which he had received in 1202 by arrangement with his elder brother Henry. The conquest of Hamburg by the Danes, and the death of John of England, were further blows to his cause. On May 19, 1218, he died at the Harzburg after being loosed from the ban by a Cistercian monk, and was buried in the church of St. Blasius at Brunswick. He left no children.

OTTO, king of Greece (1815–1867), second son of Louis I., king of Bavaria, and his wife Teresa of Saxe-Altenburg, was born at Salzburg on June 1, 1815, and was educated at Munich. In 1832 he was chosen by the conference of London to occupy the newly-erected throne of Greece, and on Feb. 6, 1833, he landed at Nauplia, then the capital of independent Greece. Otto, who was not yet eighteen, was accompanied by a council of regency composed of Bavarians under the presidency of Count Josef Ludwig von Armansperg (1787–1853). In 1835 Otto came of age, but, on the advice of his father and under pressure of Great Britain and of the house of Rothschild, who all believed that a capable finance minister was the supreme need of Greece, he retained Armansperg as chancellor of state. The Greeks were more heavily taxed than under Turkish rule; they had exchanged government by the sword, which they understood, for government by official regulations, which they hated; they had escaped from the sovereignty of the Mussulman to fall under that of a devout Catholic, to them a heretic. Otto was well intentioned, honest and inspired with a genuine affection for his adopted country; but it needed more than mere amiable qualities to reconcile the Greeks to his rule.

In 1837 Otto married Princess Amalie of Oldenburg, who made herself unpopular by interfering in the government. Meanwhile Armansperg had been dismissed by the king, but a Greek minister was not put in his place, and the granting of a constitution was postponed. The attempts of Otto to conciliate Greek sentiment by efforts to enlarge the frontiers of his kingdom, *e.g.*, by the suggested acquisition of Crete in 1841, only succeeded in embroiling him with the powers. His power rested wholly on Bavarian bayonets; and when, in 1843, the last of the German troops were withdrawn, he was forced by the outbreak of a revolutionary movement in Athens to grant a constitution and to appoint a ministry of native Greeks.

For the British blockade of the Peiraeus and Greek intervention in the Crimean War *see* GREECE: *History*. Otto's position in Greece became untenable. In 1861 a student named Drusios attempted to murder the queen, and was hailed by the populace as a modern Harmodius. In October 1862 the troops in Acarnania under General Theodore Srivas declared for the king's deposition; those in Athens followed suit; a provisional government was set up and summoned a national convention. The king and queen, who were at sea, took refuge on a British warship, and returned to Bavaria, where, on July 26, 1867, Otto died.

Mendelssohn-Bartholdy, "Die Verwaltung König Ottos von Griechenland und sein Sturz" (in *Preuss. Jahrbücher*, iv. 365); K. T. v. Heigel, *Ludwig I., König von Baiern*, pp. 149 *et seq.* (Leipzig, 1872); H. H. Parish, *The Diplomatic History of the Monarchy of Greece from the Year 1830* (London, 1838).

OTTO OF FREISING (1114?–1158), German bishop and chronicler, was the fifth son of Leopold III., margrave of Austria, by his wife Agnes, daughter of the emperor Henry IV. By her first husband, Frederick I. of Hohenstaufen, duke of Swabia, Agnes was the mother of the German king Conrad III., and grandmother of the emperor Frederick I.; and Otto was thus related to the most powerful families in Germany. He studied in Paris, and became abbot of the Cistercian monastery of Morimond in Burgundy about 1136, soon afterwards being elected bishop of Freising. In 1147 he took part in the disastrous crusade of Conrad III., returning to Bavaria in 1148 or 1149. He enjoyed the favour of Conrad's successor, Frederick I.; was probably instrumental in settling the dispute over the duchy of Bavaria in 1156; was present at the famous diet at Besancon in 1157, and died at Morimond on Sept. 22, 1158.

Otto wrote a *Chronicon*, sometimes called *De duabus civitatibus*, an historical and philosophical work in eight books, which follows to some extent Augustine and Orosius. It goes down to 1146, and from this date until 1209 has been continued by Otto, abbot of St. Blasius (d. 1223). Of the *Gesta Friderici imperatoris* the first two books were written by Otto, and the remaining two probably by his pupil Ragewin, or Rahewin. First printed by John Cuspinian at Strasbourg in 1515, Otto's writings are now issued in the *Monumenta Germaniae historica*, Band xx. (Hanover, 1868); German trans. by H. Kohl (Leipzig, 1881–86). The *Gesta Friderici* has been published separately with introduction by G. Waitz.

See J. Hashagen, *Otto von Freising als Geschichtsphilosoph und Kirchenpolitiker* (Leipzig, 1900); J. Schmidlin, *Die geschichtsphilosophische und kirchenpolitische Weltanschauung Otto von Freising* (Freiburg i./B., 1906); A. Hofmeister, "Studien über O. v. Freising" in *Gesellschaft für ältere deutsche Geschichtskunde* (Hanover, 1911); A. Potthast, *Bibliotheca historica* (1896).

OTTO OF NORDHEIM (d. 1083), duke of Bavaria, belonged to the rich and influential Saxon family of the counts of Nordheim, and received the duchy of Bavaria from Agnes, widow of the emperor Henry III., in 1061. In 1062 he assisted Anno, archbishop of Cologne, to seize the German king, Henry IV.; led a successful expedition into Hungary in 1063; and took a prominent part in the government during the king's minority. In 1064 he went to Italy to settle a papal schism, secured the banishment from court of Adalbert, archbishop of Bremen, and crossed the Alps in the royal interests on two other occasions. In 1070 Otto was accused of being privy to a plot to murder the king, and was required to submit to the ordeal of battle with his accuser. The duke asked for a safe-conduct to and from the place of meeting, and when this was refused he declined to appear, and was consequently deprived of Bavaria, while his Saxon estates were plundered. He obtained no support in Bavaria, but raised an army among the Saxons and carried on a campaign of plunder against Henry until 1071, when he submitted; in the following year he received back

his private estates. When the Saxon revolt broke out in 1073 Otto is represented by Bruno, the author of *De bello Saxonico*, as delivering an inspiring speech to the assembled Saxons at Wormsleben, after which he took command of the insurgents. By the peace of Gerstungen in 1074 Bavaria was restored to him; he shared in the Saxon rising of 1075, after which he was again pardoned and made administrator of Saxony. After the excommunication of Henry IV. in 1076 Otto attempted to mediate between Henry and the Saxons; but when these efforts failed he again placed himself at their head. He assented to the election of Rudolph, count of Rheinfelden, as German king, when his restoration to Bavaria was assured, and by his skill and bravery inflicted defeats on Henry's forces at Mellrichstadt, Flarchheim and Hohenmölsen. He remained in arms against the king until his death on Jan. 11, 1083. By his wife Richenza, widow of Hermann, count of Werla, he left six children.

See H. Mehmel, *Otto von Nordheim, Herzog von Bayern* (Göttingen, 1870); E. Neumann, *De Ottone de Nordheim* (Breslau, 1871); and A. Vogeler, *Otto von Nordheim* (Göttingen, 1880).

OTTOMAN BANK. The establishment of the "Imperial Ottoman Bank" was authorized by *Firman* in 1863 and effected by a Convention between the Turkish Government and a banking consortium of the English and French founders. Its function then was to act as the State Bank of the Turkish Empire. It was granted the exclusive right of note issue, but this has since been transferred to the Central Bank of the Republic.

In 1925 the concession under which the bank works was extended, with certain modifications, for ten years. At the same time the title "Imperial" was dropped, and the institution is now known as the "Ottoman Bank." Subsequently a further extension was made to 1952. Its legal domicile is Istanbul; the directing committees reside and meet in London and Paris, in which cities the bank has important offices. It has also a branch at Manchester and branches at Marseilles and Nice. In addition the bank has branches in Turkey (27), Egypt (8), Cyprus (6), 'Iraq (3), Palestine (5), Greece (1), Iran (2), and Transjordan (1). A subsidiary institution, the Banque de Syrie et du Liban, has about 15 branches throughout Syria. The Ottoman Bank is actively interested in the Banque Franco-Serbe, The Bank of Rumania Ltd., and the British-French Discount Bank Ltd. The capital of the bank is £10,000,000, of which half is paid up, the reserve is £1,250,000. The Ottoman Bank maintains its character as an Anglo-French institution. (C. E. L. C.; X.)

OTTOMAN EMPIRE, the empire founded by Osman (1288–1320), which lasted six centuries and a half, and fell before the democratic movement inaugurated at Angora in 1919 by Mustafa Kemal Pasha. (*See* MUSTAFA KEMAL ATATÜRK; TURKEY.)

OTTRELITE (from Ottrez, Belgium, the original locality), in mineralogy, a member of a group of closely related minerals with the general composition H_2O. RO. Al_2O_3. SiO_2, in which RO is dominantly FeO, but is often in part represented by a content of MgO or MnO. On account of its petrographic importance the term ottrelite is often used as the group name for this series of minerals, though the name clintonite is also in use. The chief members are chloritoid (H_2 Fe Al_2 SiO_7), sismondine (H_2 [Fe, Mg] Al_2SiO_7) in which the magnesia rises to 7%, and ottrelite the manganiferous variety (H_2[FeMn] Al_2SiO_7) in which the MnO content may rise to 8%. They are grey, green or black micaceous minerals, but in distinction from the "elastic" micas and "flexible" chlorites they are often referred to as the "brittle micas" on account of the brittleness of their laminae. Like the micas and chlorites they possess monoclinic symmetry and a perfect cleavage parallel to the flat surface (001) of the plates. Their superior hardness (H=6·5) readily distinguishes them from both these groups of minerals. Multiple twinning on the mica law is exceedingly common, and a zonal structure (often of hour-glass type) is often apparent. The ottrelite group of minerals is confined to metamorphic rocks—particularly those developed in regional metamorphism—in slates, phyllites and schists. Noteworthy occurrences of this mineral are the slates of the Ardennes, of Tintagel (Cornwall) and in the Mesozoic and Permian schists of the Swiss and Italian Alps.

The minerals margarite, xanthophyllite and kossmatite show some relations with the ottrelite group of minerals. They are distinguished by an inferior hardness and contain calcium as an essential constituent. Margarite (H_2Ca Al_4Si_2 O_{12}) occurs in white pearly scales associated with corundum and is a common mineral of emery deposits. Xanthophyllite occurs in talc-chlorite schists at Slatoust in the Urals and in altered limestone at Riverside, California, while kossmatite is a recently described lime-rich mineral (H=2·5) occurring in the dolomite marbles of West Macedonia. (C. E. T.)

OTTUMWA, a city of southeastern Iowa, U.S., on the Des Moines river, at an altitude of 650 ft.; the county seat of Wapello county. It is on federal highways 34 and 63, and is served by the Burlington Route, the Chicago, Milwaukee, St. Paul and Pacific, the Rock Island and the Wabash railways. Pop., 1950 federal census, 33,631. The city is built on a series of terraces rising from the river. It is in the bituminous coal fields of Iowa, at the heart of the corn and meat producing area of the middle west. Meat products, serum, agricultural implements, boilers, car loaders, hoisting engines, chicken coops, lawn mowers, mine equipment and supplies and carpenters' squares are among the leading manufactures. The aggregate factory product in 1950 was valued at $150,000,000.

Ottumwa was founded in 1843, incorporated as a town in 1851, and chartered as a city in 1857. The name is a modification of an Indian word meaning "rippling water."

OTUQUIAN, a tribe or small group of tribes of South American Indians, constituting an independent linguistic stock, so called from the Otuquis, the most important tribe. The group, which was nearly extinct in the early part of the 19th century, lived in north-eastern Bolivia in the eastern portion of the province of Chiquitos, on the Otuquis river and between it and the Paraguay, between 17° and 18° S. lat. At that time the remnant of the people were located at the mission of Santa Corazon de Chiquitos, and had already lost their original culture.

See G. L. Kriegk, *Das Land Otuquis in Bolivia* (Frankfurt, 1838); G. de Crequi-Montfort and P. Rivet, "Le groupe Otuke" (*J. Soc. Americanistes de Paris* [n.s.] vol. ix., pp. 317–337); *ibid.*, "Les affinités des dialectes Otuke" (*ibid.* vol. x., pp. 369–377).

OTWAY, THOMAS (1652–1685), English dramatist, was born at Trotten, near Midhurst, Sussex, on March 3, 1652. His father, Humphrey Otway, was at that time curate of Trotton, but Otway's childhood was spent at Woolbeding, a parish 3 m. distant, of which his father had become rector. He was educated at Winchester College, and in 1669 entered Christ Church, Oxford, as a commoner, but left the university without a degree in the autumn of 1672. In 1675 Thomas Betterton produced at Dorset Garden theatre Otway's first drama, *Alcibiades*, which was printed in the same year. It is a poor tragedy saved from absolute failure by the actors. He made a great advance on this first work in *Don Carlos, Prince of Spain* (licensed June 15, 1676; an undated edition probably belongs to the same year). In it the two characters familiar throughout his plays make their appearance. Don Carlos is the impetuous, unstable youth, who seems to be drawn from Otway himself, while the queen's part is the gentle pathetic character repeated in his more celebrated heroines, Monimia and Belvidera. In 1677 Betterton produced two adaptations from the French by Otway, *Titus and Berenice* (from Racine's *Bérénice*), and the *Cheats of Scapin* (from Molière's *Fourberies de Scapin*). These were printed together, with a dedication to Lord Rochester. In 1678 he produced an original comedy, *Friendship in Fashion*, popular at the moment, though it was hissed off the stage for its gross indecency when it was revived at Drury Lane in 1749.

Meanwhile he had conceived an overwhelming passion for Mrs. Barry, who filled many of the leading parts in his plays. Six of his letters to her survive, the last of them referring to a broken appointment in the Mall. In 1678, driven to despair by her, Otway obtained a commission through Charles, earl of Plymouth, a natural son of Charles II., in a regiment serving in the Netherlands. The English troops were disbanded in 1679, but

were left to find their way home as best they could. They were also paid with depreciated paper, and Otway arrived in London late in the year, ragged and dirty, a circumstance utilized by Rochester in his "Sessions of the Poets," which contains a scurrilous attack on his former protégé.

Early in the next year (February 1680) was produced at Dorset Garden the first of Otway's two tragic masterpieces, *The Orphan, or The Unhappy Marriage,* Mrs. Barry playing the part of Monimia. Written in blank verse, which shows a study of Shakespeare, its success was due to the tragic pathos, of which Otway was a master, in the characters of Castalio and Monimia. *The History and Fall of Caius Marius,* produced in the same year, and printed in 1692, is a curious grafting of Shakespeare's *Romeo and Juliet* on the story of Marius as related in Plutarch's *Lives.* In 1680 Otway also published *The Poet's Complaint of his Muse, or A Satyr against Libells,* in which he retaliated on his literary enemies. An indifferent comedy, *The Soldier's Fortune* (1681), was followed in February 1682 by *Venice Preserved, or A Plot Discover'd.* The story is founded on the *Histoire de la conjuration des Espagnols contre la Venise en 1618,* by the Abbé de Saint-Réal, but Otway modified the story considerably. The character of Belvidera is his own, and the leading part in the conspiracy, taken by Bedamor, the Spanish ambassador, is given in the play to the historically insignificant Pierre and Jaffier. The piece has a political meaning, enforced in the prologue. The Popish Plot was in Otway's mind, and Anthony, 1st earl of Shaftesbury, is caricatured in Antonio. The play won instant success. It was translated into almost every modern European language, and even Dryden said of it: "Nature is there, which is the greatest beauty."

The Orphan and *Venice Preserved* remained stock pieces on the stage until the 19th century, and the leading actresses of the period played Monimia and Belvidera. One or two prefaces, another weak comedy, *The Atheist* (1684), and two posthumous pieces, a poem, *Windsor Castle* (1685), a panegyric of Charles II., and a *History of the Triumvirates* (1686), translated from the French, complete the list of Otway's works. He apparently ceased to struggle against his poverty and misfortunes. The generally accepted story regarding the manner of his death was first given in Theophilus Cibber's *Lives of the Poets.* He is said to have emerged from his retreat at the Bull on Tower Hill to beg for bread. A passer-by, learning who he was, gave him a guinea, with which Otway hastened to a baker's shop. He began too hastily to satisfy his ravenous hunger, and choked with the first mouthful. Whether this account of his death be true or not, it is certain that he died in the utmost poverty, and was buried on April 16, 1685, in the churchyard of St. Clement Danes. A tragedy entitled *Heroick Friendship* was printed in 1686 as Otway's work, but the ascription is unlikely.

The Works of Mr. Thomas Otway with some account of his life and writings, published in 1712, was followed by other editions (1757, 1768, 1812). The standard edition is that by T. Thornton (1813). A selection of his plays was edited for the Mermaid series (1891 and 1903) by Roden Noel. *See* E. Schumacher, *Thomas Otway* (Bonn, 1924).

OUBLIETTE, a French architectural term used in two senses, of a dungeon in a prison or castle which could only be reached by a trap-door from another dungeon, and of a concealed opening or passage leading from a dungeon to the moat or river, into which bodies of prisoners might be dropped. Many so-called "oubliettes" in mediaeval castles were in reality the cesspools or receptacles of the castle latrines.

OUDENARDE, a town of Belgium in the province of East Flanders, 18 mi. S. of Ghent. Pop. (1939) 6,483. Known for the victory by Marlborough and Eugene over the French under Vendôme in 1708, Oudenarde has other features of interest. The town hall, which took ten years to build (1525–1535), has after that of Louvain the most elaborately decorated façade in Belgium. It was designed by H. van Peede and G. de Ronde, and is in tertiary Gothic style. The belfry tower of five storeys with three terraces, surmounted by a golden figure, is a striking feature. The council chamber contains a fine oak door and Gothic chimneypiece, both *c.* 1530. There are also two interesting old churches, St. Walburga, partly of the 12th and partly of the 14th century, and Our Lady, dating from the 13th century. The former contains several pictures by Craeyer and other Flemish masters.

The Battle of Oudenarde (June 30–July 11, 1708) was fought on the ground north-west and north of the town, which was then regularly fortified and was garrisoned by a force of the Allies. For an account of the strategic situation which led up to the battle, *see* SPANISH SUCCESSION, WAR OF THE. The French army under the duke of Burgundy and Marshal Vendôme, after an abortive attempt to invest Oudenarde, took up a defensive position north of the town when Marlborough and Eugene, after a forced march, arrived with the main Allied army. The advanced guard of the Allies under General (Lord) Cadogan promptly crossed the Scheldt, annihilated an outlying body of French troops, and established itself on the ground it had won, in front of the French centre. But the Allied main army took a long time to defile over the Scheldt and could form up (on the left of Cadogan's detachment) only slowly and by degrees. Observing this, Burgundy resolved to throw forward his right towards Oudenarde to engage and hold the main body of the Allies before their line of battle could be formed. This effected, it was hoped that the remainder of the French army could isolate and destroy Cadogan's detachment, which was already closely engaged with the French centre. But he miscalculated both the endurance of Cadogan's men (amongst whom the Prussians were conspicuous for their tenacity) and the rapidity with which in Marlborough's and Eugene's hands the wearied troops of the Allies could be made to move. Marlborough, who personally directed the operations on his left wing, not only formed his line of battle successfully, but also began seriously to press the forces that had been sent to check his deployment. Before long, while the hostile left wing still remained inactive, the unfortunate troops of the French centre and right were gradually hemmed in by the whole force of the Allies. The decisive blow was delivered by the Dutch marshal, Overkirk, who was sent by Marlborough with a large force (the last reserve of the Allies) to make a wide turning movement round the extreme right of the French, and at the proper time attacked them in rear. A belated attempt of the French left to intervene was checked by the British cavalry, and the pressure on the centre and right, which were now practically surrounded, continued even after nightfall. A few scattered units managed to escape, and the left wing retreated unmolested, but at the cost of about 3,000 casualties the Allies inflicted a loss of 6,000 killed and wounded and 9,000 prisoners on the enemy, who were, moreover, so shaken that they never recovered their confidence to the end of the campaign. The battle of Oudenarde was not the greatest of Marlborough's victories, but it affords almost the best illustration of his military character. Contrary to all the rules of war then in vogue, he fought a piecemeal and unpremeditated battle, with his back to a river, and with wearied troops, and succeeded.

OUDINÉ, EUGÈNE ANDRÉ (1810–1887), French sculptor and medallist, was born in Paris in 1810, and devoted himself from the beginning to the medallist's branch of sculpture, although he also excelled in monumental sculpture and portrait busts. He gained the grand prize for medal engraving in 1831, and in the same year exhibited his "Wounded Gladiator." He subsequently occupied official posts as designer to the Inland Revenue and to the Mint. His most famous medals are those struck in commemoration of the annexation of Savoy by France and of the peace of Villafranca. Others are "The Apotheosis of Napoleon I.," "The Universal Exposition," "The Establishment of the Republic," and "Napoleon's Tomb at the Invalides." Oudiné, who may be considered the father of the modern medal, died in 1887.

OUDINOT, CHARLES NICOLAS (1767–1847), duke of Reggio, marshal of France, was born at Bar-le-duc, on April 25, 1767. He served in the regiment of Médoc from 1784 to 1787, retiring with the rank of sergeant. On the outbreak of war in 1792 he became lieutenant colonel in the volunteers of the Meuse, being transferred to the regular army after his defence of the fort of Bitsch (1792). He was promoted general of brigade in June 1794, after the battle of Kaiserslautern. He served on the German frontier under Hoche, Pichegru and Moreau, and in the

Swiss campaign of 1799 with Masséna. He was made inspector general of infantry, and in the war of 1805 he commanded the famous "grenadiers Oudinot," with which he seized the Vienna bridges, and gave the decisive blow at Austerlitz. In 1808 he was made governor of Erfurt and count of the empire, and in 1809 after Wagram, he was promoted marshal. He was made duke of Reggio, and received a large money grant in April 1810. Oudinot governed Holland from 1810 to 1812, and commanded the II corps of the *Grande Armée* in the Russian campaign. For his defeat at Grossbeeren *see* NAPOLEONIC CAMPAIGNS. He was superseded by Marshal Michel Ney, who was defeated at Dennewitz. Oudinot again held important commands at Leipzig and in the 1814 campaign. He was made a peer under Louis XVIII, and did not join Napoleon in 1815. His last active service was in the French invasion of Spain in 1823, in which he commanded a corps, and was for a time governor of Madrid.

OUIDA, the pen name—derived from a childish attempt to pronounce "Louisa"—of Maria Louise [de la] Ramée (1839–1908), English novelist, born at Bury St. Edmunds, where her birth was registered on Jan. 7, 1839. Her father, Louis Ramée, was French, and her mother, Susan Sutton, English. In 1860 her first story, afterwards republished as *Held in Bondage* (1863), appeared in the *New Monthly* under the title of *Granville de Vigne,* and this was followed in quick succession by *Strathmore* (1865), *Chandos* (1866) and *Under Two Flags* (1867). The list of Ouida's subsequent works is a very long one; but it is sufficient to say that, together with *Moths* (1880), those already named are not only the most characteristic, but also the best. In a less dramatic genre, her *Bimbi: Stories for Children* (1882) may also be mentioned; but it was by her more flamboyant stories, such as *Under Two Flags* and *Moths,* that her popular success was achieved. She died at Viareggio, Jan. 25, 1908.

OULU, a seaport and industrial town of Finland on the Gulf of Bothnia in 65° N., 25° 29′ E., linked by rail to Helsinki. Pop. (1940) 30,315. It is the chief town of a forested department of the same name. The accommodation in the harbour depends on the wind. The exports are timber, tar, leather, flour and wood products and the imports colonial produce, coals, iron, hides and salt.

OUNCE. (1) A unit of weight, being the twelfth part of a pound troy, = 480 grains (through O. Fr. *unce,* modern *once,* from Lat. *uncia,* twelfth part, of weight, of a pound, of measure, of a foot, in which sense it gives the O. Eng. *ynce,* inch); in avoirdupois = 437.5 grains, $\frac{1}{16}$ of a pound. The *fluid ounce* is a measure of capacity; in the United Kingdom it is equivalent to an avoirdupois ounce of distilled water at 62° F.; in the United States of America it is the 128th part of the gallon, = $\frac{1}{4}$ gill, = 456.033 grains of distilled water at its maximum density (*see* MEASURES AND WEIGHTS). (2) A name properly applied to the *Panthera uncia* or snow-leopard (*q.v.*) It appears to have been originally used of various species of lynx, and is still sometimes the name of the Canada lynx.

OUNDLE (a corruption of "Avondale"), a town of Northamptonshire, England, 27 mi. N.N.E. of Northampton on the London Midland Region railway. Pop. (1951) 2,224; area 3.6 sq.mi. The manor, with a market and tolls, belonged to the abbot of Peterborough. After the Dissolution they were granted to John, earl of Bedford, and the market still belongs to the lord of the manor. The Church of St. Peter has Early English, Decorated and Perpendicular porticos. Oundle school was founded in 1556 under the will of Sir William Laxton, lord mayor of London, and in 1930 was granted a royal charter.

OURO PRETO ("Black Gold"), a city of the state of Minas Gerais, Brazil, 336 mi. by rail N. by W. of Rio de Janeiro, and about 300 mi. W. of Vitória, Espírito Santo, on the eastern slope of the Serra do Espinhaço and within the drainage basin of the Rio Doce. Pop. (1950) of city 9,247 and *município* 34,154. The city is built upon the lower slope of the Serra do Ouro Preto, a spur of the Espinhaço, deeply cut by ravines and divided into a number of irregular hills, up which the narrow, crooked streets are built and upon which groups of houses form each a separate nucleus. From a mining settlement the city grew as the inequalities of the site permitted. The rough streets are too steep and narrow for vehicles. The climate is subtropical and humid, though the elevation (3,700–3,800 ft.) gives a temperate climate in winter. The days are usually hot and the nights cold. Ouro Preto has several historic buildings; the more noteworthy are the old government house (occupied by the school of mines), the legislative chambers, municipal hall and prison—all fronting on the Praça da Independencia—the old Casa dos Contos (afterward the public treasury), a theatre (the oldest in Brazil, restored in 1861–62) and a hospital.

There are 15 churches in the city, all dating from more prosperous days. Ouro Preto is the seat of one of Brazil's leading schools of mines, in connection with which there is a museum containing an outstanding collection of native minerals.

The city dates from 1701, when a gold-mining settlement was established in its ravines by Antonio Dias of Taubaté. The circumstance that the gold turned black on exposure to the humid air (owing to the presence of silver) gave the name of Ouro Preto to the mountain spur and the settlement. In 1711 it became a city with the name of Vila Rica, a title justified by its size and wealth. In 1720 Vila Rica became the capital of the newly created captaincy of Minas Gerais, and in 1823 the capital of the province of the same name under the empire of Dom Pedro I. When the empire was overthrown in 1889 and Minas Gerais was reorganized as a republican state, it was decided to remove the capital to a more favourable site and Belo Horizonte was chosen, but Ouro Preto remained the capital until 1898, when the new town (also called Cidade de Minas) became the seat of government. In 1933 the town was decreed a national monument and the region in which it lies a national park. (*See* MINAS GERAIS.)

OUSE, the name of several English rivers, an ancient word of disputed etymology.

(1) The Great Ouse rises in Northamptonshire, in the hills between Banbury and Brackley, and falls about 500 ft. in 156 mi. to its mouth in the Wash (North sea). It flows east past Brackley and Buckingham and then turns northeast to Stony Stratford, receiving the Tove and the Ouzel at Newport Pagnell. It then follows a sinuous course past Olney to Sharnbrook, where it turns abruptly south to Bedford, then to flow northeast past St. Neot's to Godmanchester and Huntingdon, when the river trends easterly to St. Ives. Hitherto the Ouse has watered an open valley, but below St. Ives the river debouches suddenly upon the Fens; its fall from this point to the mouth, a distance of 55 mi. by the old course, is little more than 20 feet. From Earith to Denver the waters of the Ouse flow almost wholly in two straight artificial channels called the Bedford rivers, the old course being called the Old West river. This is joined by the Cam 4 mi. above Ely. North of this point the river receives the Lark, the Little Ouse, or Brandon river, and the Wissey. Below Denver sluice, 16 mi. from the mouth, the Ouse is tidal. It flows past King's Lynn, and enters the Wash near the southeast corner. The river is locked up to Bedford, a distance of 74½ mi. by the direct course. An attempt to clear the river in order to make it more navigable and less liable to floods was made, but met with opposition from the farmers of the upper reaches.

(2) A river of Yorkshire. The river Ure, rising in the Pennines, and traversing Wensleydale, unites with the river Swale to form the Ouse near Boroughbridge, in the central plain of Yorkshire. The course of the Swale, which rises on the eastern flank of the Pennines, is mostly through this plain, and that of the Ouse is wholly so. It flows southeast passing York, Selby and Goole to the Trent, to form with the river the Humber estuary (*q.v.*). The course of the Ouse, thus defined, is 45 mi. The Swale and Ure are respectively 60 mi. and 50 mi. long. Goole is a growing port, and the river bears much traffic up to York, smaller traffic up to Boroughbridge, from which the Ure Navigation (partly a canal) continues up to Ripon. The Swale is not navigable. The chief tributaries are the Nidd, the Wharfe, the Don and the Aire on the right, and the Derwent on the left. All traverse beautiful valleys, and the Aire and the Don, with canals, afford communications between south Yorkshire and the Humber ports. The Derwent is also navigable. It is tidal up to Naburn, 37 mi. from the junction with the Trent.

(3) A river of Sussex, rising in the Forest Ridges between Horsham and Cuckfield, and draining part of the Weald. Like other streams here, it breaches the South Downs, and reaches the English channel at Newhaven after a course of 30 mi. The Ouse is navigable for small vessels to Lewes, and Newhaven is an important harbour.

OUSEL or **OUZEL,** the ancient name of the blackbird, but now applied, in combination, to the dipper (*q.v.*) or water-ousel, and to the ring-ousel (*Turdus torquatus*). This latter is a relative of the blackbird. The water-ousels (*Cinclidae*) are found near mountain streams in Europe and northern Asia, in the western United States, Central and South America.

OUSELEY, SIR FREDERICK ARTHUR GORE (1825–1889), English composer, son of Sir Gore Ouseley, ambassador to Persia, was born on Aug. 12, 1825, in London. He was a precocious child, and composed an opera at the age of eight years. Educated at Christ Church, Oxford, he took orders, and held two London curacies. In 1855 he succeeded Sir Henry Bishop as professor of music in the University of Oxford, was ordained priest and appointed precentor of Hereford. In 1856 he became vicar of St. Michael's, Tenbury, and warden of St. Michaels college. His works include the oratorio *Polycarp,* written for his Mus. Doc. degree (1854), a second oratorio, *Hagar* (Hereford, 1873), a great number of services and anthems, chamber music, songs, etc., and theoretical works. He died on April 6, 1889.

His uncle, SIR WILLIAM OUSELEY (1769–1842), British orientalist, wrote *Travels in Various Countries in the East, Especially Persia, in 1810, 1811 and 1812* (3 vol., 1819–23).

OUSTER, a legal term signifying dispossession, especially the wrong or injury suffered by a person dispossessed of freeholds or chattels real. The wrongdoer by getting into occupation forces the real owner to take legal steps to regain his rights. Ouster of the freehold may be effected by *abatement, i.e.,* by entry on the death of the person seized before the entry of the heir, or devisee; by *intrusion,* entry after the death of the tenant for life before the entry of the reversioner or remainderman; by *disseisin,* the forcible or fraudulent expulsion of the occupier or person seized of the property. Ouster of chattels real is effected by *disseisin,* the turning out by force or fraud of the legal proprietor before his estate is determined. Ouster by force, or forcible entry, was made a criminal offense by a statute of 1381.

OUTLAWRY, the process of putting a person out of the protection of the law; a punishment for contemptuously refusing to appear when called in court, or evading justice by disappearing. It was of very early existence in England, and was the punishment of those who could not pay the *were* or blood-money to the relatives of the deceased. By the Saxon law, an outlaw lost his *libera lex* and had no protection from the frank-pledge in the decennary in which he was sworn. He was, too, a *frendlesman,* because he forfeited his friends; for if any of them rendered him any assistance, they became liable to the same punishment. An outlaw was *civiliter mortuus.*

He could not sue in any court, nor had he any legal rights which could be enforced, but he was personally liable upon all causes of action. It was finally abolished in civil proceedings in 1879, while in criminal proceedings it has practically become obsolete, being unnecessary through the general adoption of extradition treaties.

In Scotland outlawry or fugitation may on the motion of the crown be pronounced by the supreme criminal court when the panel has absconded and fails to appear to plead to the indictment on the day of trial.

OUTLAWRY OF WAR. When, under the older conceptions of international law, nations went to war, their inter-state relations were regulated, for the period of belligerency, by the law of war instead of by the law of peace. "International law," writes Professor F. L. Schuman (*International Politics, An Introduction to the Western State System,* p. 109) "does not justify or sanction war but recognizes it as a fact of international politics and seeks to restrict and mitigate its cruel and destructive features." He goes on to point out that on the whole the principles of international law, governing the conduct of hostilities, have been reasonably well observed despite appearances to the contrary, the motives probably being expediency and fear of retaliation on the part of the belligerents. This is the case even where there is no formal declaration of war, as in the Sino-Japanese hostilities.

In the late twenties a group of American authorities interested in peace came to feel that the resort to war would be less likely if it were formally deprived of its legal status and definitely "outlawed." The advocates of the outlawry of war theory felt that so long as the institution of war remained respectable and enjoyed a recognized place in the field of international relations, the root of the evil remained.

Their solution of the problem was, in part, to oust war from its privileged position by denying it a legal status and placing a state indulging in hostilities against another state beyond the pale, that is to say, literally to outlaw it.

Among the principal advocates of the outlawry of war movement in the United States were Judge Florence E. Allen, Senator William E. Borah, Dr. Nicholas Murray Butler, Professor John Dewey, Reverend John Haynes Holmes, S. O. Levinson, Dr. C. C. Morrison, Reverend M. V. Oggel and the American Committee for the Outlawry of War.

The draft treaty to outlaw war which this last named committee suggested as a basis for discussion provided that the signatory states would:—

"... condemn and abandon forever the use of war as an instrument for the settlement of international disputes and for the enforcement of decisions and awards of international tribunals, and hereby outlaw the immemorial institution of war by making its use a public crime as the fundamental law of nations."

would

". . . agree to take immediate action for the equipment of an international court of justice with a code of the laws of peace . . . jurisdiction over all purely international disputes as defined and enumerated in the code or arising under treaties, with power to summon in a defendant nation at the petition of a complaining nation and to hear and decide the matters in controversy."

and would

"agree to abide by and in full good faith to carry out the decisions of such international tribunal[1]. . .,"

thus dropping the idea of other than moral sanctions for the enforcement of the outlawry of war plan.

The statesman primarily responsible for the idea of bringing about the renunciation of war by means of an *ad hoc* treaty was Aristide Briand, French minister of foreign affairs. On June 20, 1927, Briand proposed to the United States the conclusion of a bilateral treaty covering the ground suggested by the advocates of the outlawry of war.

In replying to this proposal the United States suggested that instead of contenting themselves with a bilateral declaration of the nature suggested by Briand, the two governments might make a more signal contribution to world peace by joining in an effort to obtain the concurrence therein of a large group of powers with a view to perfecting among all the nations of the world a mechanism for peace heretofore suggested only as between France and the United States.

The draft multilateral anti-war treaty proposed by the United States on June 23, 1928, was promptly accepted by 14 other governments and signed at Paris on Aug. 27, 1928. Its terms were as follows:

ARTICLE I.

"The High Contracting Parties solemnly declare in the names of their respective peoples that they condemn recourse to war for the solution of international controversies, and renounce it as an instrument of national policy in their relations with one another.

ARTICLE II.

"The High Contracting Parties agree that the settlement or solution of all disputes or conflicts of whatever nature or of whatever origin they may be, which may arise among them, shall never be sought except by pacific means.

ARTICLE III.

"The present Treaty shall be ratified by the High Contracting Parties

[1]*The Outlawry of War* by C. C. Morrison, p. 62 (Chicago, 1927).

named in the Preamble in accordance with their respective constitutional requirements, and shall take effect as between them as soon as all their several instruments of ratification shall have been deposited at Washington.

"This Treaty shall, when it has come into effect as prescribed in the preceding paragraph, remain open as long as may be necessary for adherence by all the other Powers of the world. Every instrument evidencing the adherence of a Power shall be deposited at Washington and the Treaty shall immediately upon such deposit become effective as between the Power thus adhering and the other Powers parties hereto.

"It shall be the duty of the Government of the United States to furnish each Government named in the Preamble and every Government subsequently adhering to this Treaty with a certified copy of the Treaty and of every instrument of ratification or adherence. It shall also be the duty of the Government of the United States telegraphically to notify such Governments immediately upon the deposit with it of each instrument of ratification or adherence."

The treaty was ratified by the United States senate on Jan. 15, 1929. On March 2 eleven nations deposited their ratifications at Washington. The ratifications of other nations followed rapidly so that on July 15 President Hoover set aside July 24 as the date for the formal proclamation of the treaty, and the ceremony marking the deposit of the ratifications of the 45 nations adhering to it was carried out on July 24, 1929.

Although great hopes were entertained at the time of the effect which these declarations would have in the preservation of peace, they had no observable deterrent effect upon the aggressions which shortly followed in Manchuria in 1931 or in China proper at a later stage; nor upon the Italian invasion of Ethiopia, nor upon the German-Italian interventions in Spain, nor on any of those which finally culminated in World War II. The Kellogg pact and other agreements for the renunciation of war, nowever, had one legal effect of some importance. They helped to make it expedient for states to refrain from formal declarations of war. Thus, though Japan in 1937 began to bombard Chinese cities and kill Chinese citizens in great numbers, she was not formally at "war." The bombardment and the killings were an "incident" of "intervention for the restoration of order." Other states at times followed the example so set. (N. AL.)

OUTPUT: *see* PRODUCTION, CENSUS OF.

OUTRAM, SIR JAMES (1803–1863), English general, and one of the heroes of the Indian Mutiny, was the son of Benjamin Outram of Butterley Hall, Derbyshire, civil engineer, and was born on Jan. 29, 1803. His father died in 1805, and his mother, a daughter of Dr. James Anderson, the Scottish writer on agriculture, removed in 1810 to Aberdeenshire. From Udny school the boy went in 1818 to the Marischal college, Aberdeen; and in 1819 an Indian cadetship was given him. Soon after his arrival at Bombay his remarkable energy attracted notice, and in July 1820 he became acting adjutant to the first battalion of the 12th regiment on its embodiment at Poona. In 1825 he was sent to Khandesh, where he trained a light infantry corps, formed of the wild robber Bhils, gaining over them a marvelous personal influence, and employing them with great success in checking outrages and plunder. Their loyalty to him had its principal source in their boundless admiration of his hunting achievements. For some time he was political agent in the Mahi Kantha district of Gujarat. In the first Afghan War in 1838 he was extra aide-de-camp on the staff of Sir John Keane. After conducting various raids against Afghan tribes, he was in 1839 promoted major, and appointed political agent in lower Sind, and later in upper Sind. He opposed the policy of his superior, Sir Charles Napier, which led to the annexation of Sind. When war broke out he heroically defended the residency at Hyderabad against 8,000 Baluchis; and it was Napier who then described him as "the Bayard of India."

On his return from a short visit to England in 1843, he was, with the rank of brevet lieutenant colonel, appointed to a command in the Mahratta country, and in 1847 he was transferred from Satara to Baroda, where he incurred the resentment of the Bombay government by his fearless exposure of corruption. In 1854 he was appointed resident at Lucknow, in which capacity two years later he carried out the annexation of Oudh and became the first chief commissioner of that province. Appointed in 1857, with the rank of lieutenant general, to command an expedition against Persia, he defeated the enemy with great slaughter at Khushab, and brought the campaign to a rapid conclusion.

From Persia he was summoned in June to India, with the brief explanation—"We want all our best men here." It was said of him at this time that "a fox is a fool and a lion a coward by the side of Sir J. Outram." Immediately on his arrival in Calcutta he was appointed to command the two divisions of the Bengal army occupying the country from Calcutta to Cawnpore; and to the military control was also joined the commissionership of Oudh. Already the mutiny had assumed such proportions as to compel Havelock to fall back on Cawnpore, which he only held with difficulty, although a speedy advance was necessary to save the garrison at Lucknow. On arriving at Cawnpore with reinforcements, Outram, "in admiration of the brilliant deeds of General Havelock," conceded to him the glory of relieving Lucknow, and, waiving his rank, tendered his services to him as a volunteer.

Resuming supreme command, he then held the town till the arrival of Sir Colin Campbell, after which he conducted the evacuation of the residency so as completely to deceive the enemy. In the second capture of Lucknow, on the commander in chief's return, Outram was entrusted with the attack on the side of the Gumti, and afterwards, having recrossed the river, he advanced "through the Chattar Manzil to take the residency," thus, in the words of Sir Colin Campbell, "putting the finishing stroke on the enemy." After the capture of Lucknow he was gazetted lieutenant general. In February 1858 he received the special thanks of both houses of parliament, and in the same year the dignity of baronet with an annuity of £1,000. Shattered in health he returned finally to England in 1860. He died on March 11, 1863.

OUT RELIEF: *see* POOR LAW.

OVAL: a figure or body shaped like the longitudinal section of an egg.

OVAR, a town of Portugal, at the northern extremity of the lagoon of Aveiro (*q.v.*); 21 mi. south of Oporto by the Lisbon-Oporto railway. Pop. (1950) 7,248. Ovar is the centre of important fisheries. Millet, wheat and vegetables—especially onions—are the chief products of the low-lying and unhealthy regions in which Ovar is situated.

OVARIOTOMY or **OÖPHORECTOMY,** the operation for removal of one or of both of the female ovaries (for anatomy *see* REPRODUCTIVE SYSTEM). The progress of modern surgery has been conspicuously successful in this department. From 1701, the date when Houston of Carluke, Lanarkshire, carried out his successful partial extirpation, progress was arrested for some time, although the Hunters (1780) indicated the practicability of the operation. In 1809 Ephraim McDowell of Kentucky, inspired by the lectures of John Bell, his teacher in Edinburgh, performed ovariotomy, and, continuing to operate with success, established the possibility of surgical interference. He was followed by others in the United States. The cases brought forward by Lizars of Edinburgh were not sufficiently encouraging; the operation met with great opposition; and it was not until Charles Clay, Spencer Wells, Baker Brown and Thomas Keith began work that the procedure was placed on a firm basis and was regarded as justifiable. Improved methods were introduced, and surgeons vied with one another in trying to obtain good results. Eventually, by the introduction of the antiseptic, and later, the aseptic, system of treating wounds, this operation, formerly regarded as one of the most grave and anxious in the domain of surgery, came to be attended with a lower mortality than any other of a major character.

OVEN-BIRD, the name given to birds of the genus *Furnarius* of the American family of wood-hewers (*Dendrocolaptidae*), on account of the structure of the nest. They are small thrush-like birds confined to South America.

The name oven-bird is commonly given in the United States to the golden crowned water-thrush (*Seiurus aurocapillus*), one of the wood warblers, which builds an oven-shaped nest on the

ground.

See C. Darwin, *Voyage of the Beagle* (1845); W. H. Hudson, *A Naturalist in La Plata* (1892).

OVERBECK, JOHANN FRIEDRICH (1789–1869), German painter, the reviver of "Christian art" in the 19th century, was born in Lübeck on the 4th of July 1789. His ancestors for three generations had been Protestant pastors; his father was doctor of laws, poet, mystic pietist and burgomaster of Lübeck. In 1806, after finishing his course at the gymnasium, Overbeck left Lübeck and entered the Academy of Vienna, then under the direction of Füger, a painter of the pseudo-classic school of David. Not finding the help on which he had counted, Overbeck turned to the early and pre-Raphaelite masters of Italy for inspiration. At the end of four years he was expelled. He thereupon went to live in Rome, where he gathered about him a group of friends which included Cornelius, Veit and Wilhelm Schadow.

The little group made their home in the old Franciscan monastery of San Isidoro on the Pincian, and in 1813 Overbeck joined the Roman Catholic church. The group became known as the "Nazarites," "pre-Raphaelites," or "German-Roman artists." They believed in hard, honest work and holy living, eschewed the antique as pagan and the Renaissance as false, and aimed at bringing about a revival on the basis of nature and the serious art of Perugino, Pinturicchio, Francia and the young Raphael. Their painting was characterized by nobility of conception, precision—not to say hardness—of outline, and scholarly composition. Light, shade and colour they admitted only in the interests of clearness and correctness, and not as softening elements. Overbeck, with his saintly character and lofty ideals, was the natural leader and mentor of the party. They would have fared badly however from a practical point of view but for the timely help of Niebuhr, Bunsen, Friedrich Schlegel, and the Prussian consul Bartholdi, who commissioned the four friends to decorate his villa with frescoes on the story of Joseph and his Brethren. This led to another commission from Prince Massimo to paint the ceilings and walls of his pavilion. Overbeck's failing health did not allow him to finish his share of this undertaking and he delegated it to Joseph Führich. His last work was a "Vision of St. Francis" with life-size figures for the walls of Sta. Maria degli Angeli near Assisi. All his paintings bear the mark of religious fervour and careful preparation and have an element of religious propaganda. The handling is dry and severe and the colour restrained. His faith found its clearest expression in his religious cartoons, the *Gospels* (1852), *Via Crucis* (1857) and the *Seven Sacraments* (1861). He died in Rome on Nov. 12, 1869, and was buried in San Bernardo.

Overbeck's principal oil and easel paintings are: "Christ's Entry into Jerusalem" (1824), in the Marien Kirche, Lübeck; "Christ's Agony in the Garden" (1835), in the great hospital, Hamburg; "Lo Sposalizio" (1836), Raczynski gallery, Berlin; the "Triumph of Religion in the Arts" (1840), in the Städel Institut, Frankfort; "Pietà" (1846), in the Marien Kirche, Lübeck; the "Incredulity of St. Thomas" (1851), in the possession of Mr. Beresford Hope, London; the "Assumption of the Madonna" (1855), in Cologne Cathedral; "Christ delivered from the Jews" (1858), tempera, on a ceiling in the Quirinal Palace—a commission from Pius IX., and a direct attack on the Italian temporal government, therefore later covered by a canvas.

There are biographies by J. Beavington Atkinson (1882) and Howitt (1886).

OVERBURY, SIR THOMAS (1581–1613), English poet and essayist, and the victim of one of the most sensational crimes in English history, was the son of Nicholas Overbury, of Bourton-on-the-Hill, and was born in 1581 at Compton Scorpion, near Ilmington, in Warwickshire. In the autumn of 1595 he became a gentleman commoner of Queen's college, Oxford, took his degree in 1598 and came to London to study in the Middle Temple.

About the year 1601, being in Edinburgh on a holiday, he met Robert Carr, then an obscure page to the earl of Dunbar; and the two youths came up to London together. When Carr attracted the attention of James I., in 1606, by breaking his leg in the tilt-yard, Overbury had for some time been servitor-in-ordinary to the king. He was knighted in 1608, and in 1609 travelled in France and the Low Countries. When Carr was made Lord Rochester in 1610, the intimacy between the two was maintained. But early in 1611 the Court became aware of the mutual attraction between Rochester and the youthful countess of Essex. To this intrigue Overbury was from the first violently opposed, and expressed his opinion of the countess in unmeasured terms. But Rochester was now infatuated, and he repeated to the countess what Overbury had said. Overbury also wrote, and circulated widely in ms., the poem called *The Wife*, which was a picture of the virtues which a young man should demand in a woman. The situation now resolved itself into a duel for the person of Rochester between the mistress and the friend. Overbury was thrown into the Tower on April 22, 1613, on a charge of disrespect to the king. Lady Essex, however, was not satisfied with his imprisonment; she was determined that "he should return no more to this stage." She bribed the gaoler, aided by Mrs. Turner, the widow of a physician, and by an apothecary called Franklin, to poison Overbury with copper vitriol. His constitution long withstood the timid doses they gave him, and he lingered until Sept. 15, 1613, when more violent measures put an end to his existence.

Two months later Rochester, now earl of Somerset, married Lady Essex. More than a year passed before suspicion was aroused, and when it was, the king showed disinclination to bring the offenders to justice. In the trial which followed, the plot was discovered. The four accomplices were hanged; the countess of Somerset pleaded guilty but was spared, and Somerset himself was disgraced. Meanwhile, Overbury's poem, *The Wife*, was published in 1614, and ran through six editions within a year. Much that must be spurious was added to the gathering snow-ball of Overbury's *Works*, the most famous of which are the *Characters*.

See C. Whibley, *Essays in Biography* (1913); E. A. Parry, *The Overbury Mystery* (1925).

OVERHEAD CHARGES. Overhead charges, or on-costs, are an important factor in cost accounts. Prime cost represents outlays directly incurred for a particular purpose, and thus capable of being charged directly thereto. In addition, there are a number of indirect expenses which can only be dealt with by spreading them as equitably as may be over the total output.

Generally speaking, Overhead charges consist of such items as rent, rates, taxes, salaries, depreciation, interest, discounts, bad debts, etc., from which may be deducted corresponding credits. But in order to arrive at costs that are comparable with those of similar undertakings, various adjustments become necessary. Thus, where business premises are owned, the rental value should be included, although not actually expended. When time is of importance, interest on outlays should be included, even although no interest may actually have been paid away. *Per contra*, interest on borrowed monies (including debentures) is not properly a factor in costs at all; and interest received on investments, although undoubtedly a profit, does not tend to reduce operative costs and should therefore be excluded. Many authorities also consider that bad debts have nothing to do with the costs. Depreciation of equipment is generally a very important factor but the modern tendency is to charge a *machine rate* of so much per hour as part of the direct costs, such rate being designed to cover depreciation, repairs and interest on capital; when this is done, no charge in respect of depreciation falls to be included as Overhead.

Formerly, it was thought to be sufficiently accurate to add a given percentage to prime cost as a loading to cover Overhead. It is now recognized that no satisfactory results can be achieved in this way. A uniform percentage of loading for Overhead would result in the aggregate amount actually charged against output varying directly with the prime cost, and thus the amount so charged would almost certainly be appreciably more or appreciably less than the true figure, according to whether the output was above or below the average. Further, such a system of allocation assumes that the fair loading for Overhead varies directly with the prime cost, whereas the employment of expensive materials does not necessarily increase the Overhead burden, and in many cases economies in labour costs can only be achieved by increasing the Overhead burden, *e.g.*, when machine work is substituted for hand work. Most production is complex, and consists of a series of successive processes or operations, each involving its own Overhead

charges. The modern practice is accordingly in the direction of analysing Overhead into departments, and distributing the burden of the departmental Overhead over the output of the department, usually *pro rata* according to the time occupied. In this way some approach to substantial accuracy may be reached, but no cut and dried formula will meet all cases.

Sometimes costs are appreciably increased by "spoils"—the curtailment of saleable output as a result of defective materials, machinery, workmanship or supervision. The only satisfactory way to deal with losses arising from spoils is to charge them as part of the Overhead burden of the department causing the spoil. If and when this is done the loss is thrown upon the right shoulders, and the effect commonly is to reduce very materially the loss arising from spoils by compelling managers to enquire more carefully into causes and possible remedies. (L. R. D.)

OVERSEA INVESTMENTS: *see* Capital, Export of.

OVERSEA SETTLEMENT COMMITTEE. This important body was appointed in 1919 to assist and advise the British Government in their policy of undertaking closer responsibility than they had exercised in the past in connection with the movement of British subjects wishing to settle in other parts of the empire or to emigrate to foreign countries. The functions of the Emigrants' Information Office, which was established in 1886, were absorbed by the Oversea Settlement Committee. The president of the committee is the secretary of state for dominion affairs. It is a representative and non-political body, composed partly of official members representing various Government departments and partly of unofficial members. The staff of the committee forms a department (the oversea settlement department) of the Dominions Office.

The committee is entrusted with the administration of the Empire Settlement Act, 1922, which now forms the basis of the policy of State-aided empire settlement. The act was passed as the result of a conference with representatives of the self-governing dominions in 1921 and empowers the secretary of state "in association with the Government of any part of His Majesty's Dominions, or with public authorities or public or private organisations either in the United Kingdom or in any part of such Dominions, to formulate and co-operate in carrying out agreed schemes for affording joint assistance to suitable persons in the United Kingdom who intend to settle in any part of His Majesty's Oversea Dominions." Such schemes may take the form of development or land settlement schemes, or of schemes for facilitating settlement overseas by assistance with passages, training or in other ways. The contribution of the secretary of state may not exceed half the cost of any approved scheme and the maximum expenditure allowed under the act in any one year is £3,000,000.

OVERSTONE, SAMUEL JONES LOYD, 1st Baron (1796–1883), English banker, the son of a Welsh dissenting minister, was born on Sept. 25, 1796. He became a partner in Jones, Loyd and Company (afterwards incorporated in the London and Westminster Bank), and by 1832 was recognized as one of the foremost authorities on banking. As Liberal member for Hythe, he sat in parliament from 1819 to 1826. He gave important evidence before various committees of the House of Commons, and was responsible for the main outlines of the Bank Charter Act (1844). In 1850 he was created Baron Overstone. He died in London on Nov. 17, 1883, leaving one daughter.

In 1858 a volume of *Tracts and other Publications on Metallic and Paper Currency,* by Lord Overstone, was edited by M'Culloch.

OVERT ACT: *see* Intent; Treason.

OVERTURE (Fr. *ouverture,* opening), in music, a detachable instrumental introduction to a dramatic or choral composition. The notion of an overture had no existence until the 17th century. The *toccata* at the beginning of Monteverdi's *Orfeo* is a barbaric flourish of every procurable instrument, alternating with a melodious section entitled *ritornello;* and, in so far as this constitutes the first instrumental movement prefixed to an opera, it may be called an overture. As an art-form the overture began to exist in the works of J. B. Lully. His favourite, but not his only, form constitutes the typical French overture that became classical in the works of Bach and Handel. This French overture consists of a slow introduction in a marked "dotted rhythm" (*i.e.,* exaggerated iambic, if the first chord is disregarded), followed by a lively movement in fugato style. The slow introduction was always repeated, and sometimes the quick movement concluded by returning to the slow tempo and material, and was also repeated (*see* Bach's French Overture in the *Klavierübung*).

The operatic French overture was frequently followed by a series of dance tunes before the curtain rose. It thus naturally became used as the prelude to a suite (*q.v.*); and the term was then applied to the whole suite.

Bach was able to adapt the French overture to choruses, and even to the treatment of chorales. Thus the overture—movements of his fourth orchestral suite became the first chorus of the church cantata *Unser Mund sei voll Lachens;* the choruses of the cantatas *Preise Jerusalem den Herrn* and *Höchst erwünschtes Freudenfest* are in overture form; and, in the first of the two cantatas entitled *Nun komm, der Heiden Heiland,* Bach has adapted the overture form to the treatment of a chorale.

Gluck could find no use for the French overture. In the epoch-making preface to *Alceste* he laid down the rule that the overture should be the musical argument of the drama. And the perfunctory overture to *Orfeo* is the only exception to the rule that in his great operas the orchestral introduction is actually interrupted by the rise of the curtain. In *Iphigénie en Tauride* it is merely the calm before the storm.

The abolition of the French overture did not, however, lead at first to any widespread adoption of Gluck's loose-knit Italian texture. The next form of overture was that of a three-movement symphony (*q.v.*) in sonata style. In Mozart's early opera *La Finta Giardiniera* the curtain rises upon what should have been the third movement; and in all later works the overture is distinguished from symphonic music in style as well as form. It is a single quick movement (with or without a slow introduction) in sonata form, loose in texture, without repeats, and frequently without a development section. Sometimes, in place of development, there is a melodious episode in slow time; as in Mozart's overtures to *Die Entführung* and to the fragment *Lo Sposo deluso,* in both of which cases the curtain rises at a point which throws a dramatic light upon this feature. Mozart at first intended a similar episode in the overture to *Figaro,* but struck it out as soon as he had begun it.

In Beethoven's hands the overture became more and more unlike the symphony, but it no longer remained an inferior species; and the final version of the overture to *Leonora* is the most gigantic single orchestral movement ever based on the sonata style. Weber's overtures work out prominent themes in his operas in a loose but effective sonata form, and are effective concert-pieces besides serving Gluck's purposes admirably. On the overture to Mendelssohn's *Elijah, see* Mendelssohn-Bartholdy, Jakob Ludwig Felix. Overtures to plays naturally tend to become detached from their surroundings; and hence arises the concert overture, led by Beethoven's mighty *Coriolan,* and second only to the symphony as an orchestral art-form. Its derivation implies that it is programme music (*q.v.*), but the programme need not impair the form, whether the form be Berlioz's or Brahms's, and the programme particular or generalized. Among overtures with a generalized programme Mendelssohn's *Hebrides* overture is a perfect masterpiece; and so is Brahms's Tragic overture, one of the greatest orchestral movements since Beethoven. Brahms's *Academic Festival Overture* is a glorious working out of German student songs.

In modern opera the overture, *Prelude, Vorspiel,* or whatever else it may be called, is often nothing more definite than that portion of the music which takes place before the curtain rises. *Tannhäuser* is the last important opera in which the overture retains vestiges of a self-contained sonata form. Fifty years before Wagner's wonderful *Vorspiel* to *Lohengrin,* Méhul had achieved an equally complete departure from classical forms in his interesting overtures to *Ariodant* and *Uthal,* in the latter of which a voice is heard on the stage before the rise of the curtain. Even the most self-contained of Wagner's later preludes lose by transference to the concert-room. The glorious *Vorspiel* to *Die*

Meistersinger is nobler when its long *crescendo* leads to the rise of the curtain and the engaging of all the listener's sense of sight and language, than when it can merely lead to a final tonic chord. Wagner himself added a page to finish the *Vorspiel* to *Tristan,* and by the richness and subtlety of that page he reveals how unready for independent existence the original *Vorspiel* was. He also finished the *Parsifal* Vorspiel for concert use by the addition of a few extra bars, which will always sound perfunctory. The four dramas of the *Ring* begin with introductions designed to prepare the hearer immediately for the rise of the curtain; and these works can no more be said to have overtures than Verdi's *Falstaff* and Strauss's *Salome, Electra* and *Die Frau ohne Schatten,* in which the curtain rises at the first note of the music. (D. F. T.)

OVERYSSEL, a Netherlands province, bounded south and southwest by Gelderland, west by the Zuider Zee, north by Friesland and Drente, and east by Germany. The project to connect the northeast Polder with the north of the province was in preparation when Germany invaded the Netherlands in May 1940. Pop. of the province (1938) 569,920, showing about 50% increase during the 20th century; area, 1,295 sq.mi. It is a varied glaciated delta land consisting of a sandy flat relieved by hillocks, and covered with waste stretches of heath broken by patches of wood and high fen; but the coastal strip north of Zwartsluis consists largely of low-lying fertile pasture lands with cattle-rearing and associated butter and cheese manufactures, while along the shores mats and brushes are made.

The river system is determined by two main glacial ridges, of which the eastern one, which separates the Dinkel and Regge, extends from Enschede northwards into the German enclave; the larger one runs parallel with it and commencing at Lochem (Gelderland) extends into south Drente. In the south it separates the Yssel and Regge; its summit height (Lemeler Hill, 262 ft.) is near where it is breached by the Vecht. This river crosses the province from east to west and joins a part of the Yssel near Zwolle to form the Zwarte Water, which communicates with the Zuider Zee by the Zwolsche Diep; the main Yssel enters the Zuider Zee separately below Kampen. The streams are flanked by small-estate fertile grasslands from which agriculture and cattle-rearing have gradually spread over the sand-grounds; much of the area, however, is still waste though forest culture is practised locally, especially in the east, and pigs are largely bred. The deposits of the Yssel and the Dinkel streams contain iron ore, which is extracted and exported to Germany. Peat-digging and fen reclamation have long been practised and much high fen north of the Vecht in the neighbourhood of Dedemsvaart has been reclaimed though the main reclamation at present is taking place along and near to the eastern ridge. Large scale manufactures are not important in Overyssel but cotton-spinning, together with bleaching-works, came into some prominence in the 19th century in the south-east district of Twente. The inhabitants for long had practised weaving as a home craft but capitalist Baptist refugees who arrived in the 17th and 18th centuries organized it into an industry. Deventer has iron foundries and carpet-factories but is more famed for its honey cakes. The capital of the province is Zwolle, pop. (1940) 42,136, though Enschede (90,289) is the largest town. Deventer, Hengelo and Almelo each exceed 20,000 population and all four are situated in the south. Deventer is an old but busy little river port with a 16th century weigh-house of unusual design. Kampen, on the Yssel with its harbour long since silted up, has lost much of its importance of Hanseatic days but its 14th century churches and gateways are interesting. Its Stadhuis (16th and 18th century) is probably the finest town hall in the Netherlands. It shares a fishing trade with Vollenhove and Blokzijl, all on the Zuider Zee. Tucked away in the extreme north near the Drente border is the delightful little settlement of Giethoorn, literally a water village, each house possessing its own quay, drawbridge and punt. The railway system of the province is supplemented by tramlines and the roads are good but the waterways still carry much traffic.

OVID [PUBLIUS OVIDIUS NASO] (43 B.C.–A.D. 17), Roman poet, the last of the Augustan age, was born in 43 B.C., the last year of the republic. Thus the only form of political life known to Ovid was that of the absolute rule of Augustus and his successor. He was born on March 20 at Sulmo, picturesquely situated among the mountains of the Abruzzi: its wealth of waters and natural beauties seem to have quickened in him that appreciative eye for the beauties of nature which is one of the chief characteristics of his poems. Ovid, whose father was of equestrian family, belonged by birth to the same social class as Tibullus and Propertius, that of old hereditary landowners; but he was more fortunate than they in the immunity which his native district enjoyed from the confiscations made by the triumvirs. He and his brother had been brought early to Rome for their education, where they attended the lectures of two most eminent teachers of rhetoric, Arellius Fuscus and Porcius Latro, to which influence is due the strong rhetorical element in Ovid's style. His father did his best to dissuade him from poetry, and to drive him into the legal profession.

The earliest edition of the *Amores,* which first appeared in 5 books, and the *Heroides* were given by him to the world at an early age. "Virgil," he informs us, "he had only seen"; but Virgil's friend and contemporary Aemilius Macer used to read his didactic poems to him; and even the fastidious Horace sometimes delighted his ears with the music of his verse. He had a close bond of intimacy with the younger poets of the older generation—Tibullus, whose death he laments in one of the few pathetic pieces among his earlier writings, and Propertius, to whom he describes himself as united in the close ties of comradeship. The name of Maecenas he nowhere mentions. The time of his influence was past when Ovid entered upon his poetical career. But the veteran politician Messalla, the friend of Tibullus, together with his powerful son Cotta Messallinus and Fabius Maximus and other influential persons whose names are preserved in the *Epistles from Pontus* supported him. With the older poet, Macer, he travelled for more than a year. Whether this was immediately after the completion of his education, or in the interval between the publication of his earlier poems and that of the *Medea* and *Ars amatoria* is unknown, but it is in his later works, the *Fasti* and *Metamorphoses,* that we chiefly recognize the impressions of the scenes he visited. In one of the *Epistles from Pontus* (ii. 10) to his fellow-traveller there is a vivid record of the pleasant time they had passed together. They visited Athens, of course, the Mecca of all artistic pilgrimages then; went on to the site of Troy, and through the cities of Asia Minor; and finally spent a year in Sicily.

Life in Rome.—When settled at Rome, although a public career leading to senatorial position was open to him, and although he filled various minor posts, he had no ambition for such distinction, and looked upon pleasure and poetry as the occupations of his life. He was three times married; when little more than a boy to his first wife, whom he naïvely describes as unworthy of himself; but he was soon separated from her and took a second wife, with whom his union also did not last long. She was probably the mother of his one daughter. Later he married a third, of whom he always speaks with affection and respect. She was a lady of the great Fabian house, and thus connected with his powerful patron Fabius Maximus, and was a friend of the empress Livia. It therefore seems likely that he may have been admitted into the intimacy of the younger society of the Palatine. His liaison with his mistress Corinna, whom he celebrates in the *Amores,* took place probably in the period between his first and second, or between his second and third marriages. Ovid is not only a less constant but he is a less serious lover than his great predecessors Catullus, Tibullus and Propertius. His tone is that either of mere sensuous feeling or of irony. In his complete emancipation from all restraint he goes beyond them, and thus reflects the tastes and spirit of fashionable Rome between the years 20 B.C. and the beginning of our era.

Society was then bent simply on amusement; and, as a result partly of the loss of political interests, women came to play a more important and brilliant part in its life than they had done before. Julia, the daughter of the emperor, was by her position, her wit and beauty, and her reckless dissipation, the natural

leader of such a society. But the discovery of her intrigue (2 B.C.) with Iulus Antonius, the son of Mark Antony, was deeply resented by Augustus as being at once a shock to his affections and a blow to his policy of moral reform. Julia was banished and disinherited; Antonius and her many lovers were punished; and the Roman world awoke from its fool's paradise of pleasure. Nearly coincidently with this scandal appeared Ovid's *Ars amatoria,* perhaps the most immoral work ever written by a man of genius, though not the most demoralizing, since it is entirely free from morbid sentiment. By its brilliancy and heartlessness it appealed to the prevailing taste of the fashionable world; but its appearance excited deep resentment in the mind of the emperor, as is shown by his edict, issued ten years later, against the book and its author. Ovid appears to have had no idea of the storm that was gathering over him.

But he was aware that public opinion had been shocked, or professed to be shocked, by his last work; and after writing a kind of apology for it, called the *Remedia amoris,* he turned to other subjects, and wrote during the next ten years the *Metamorphoses* and the *Fasti.* He had already written the *Heroides,* in which he had imparted a modern and romantic interest to the heroines of the old mythology, and a tragedy, the *Medea,* which must have afforded greater scope for the dramatic and psychological treatment of the passion with which he was most familiar. In the *Fasti* Ovid assumes the position of a national poet by imparting poetical life and interest to the ceremonial observances of the Roman religion; but it is as the brilliant narrator of the romantic tales that were so strangely blended with the realistic annals of Rome that he succeeds in the part assumed by him. The *Metamorphoses* is a narrative poem which recounts legends in which the miraculous involved transformations of shape. Beginning with the change from Chaos to Cosmos, legends first Greek and then Roman are passed in review, concluding with the metamorphosis of Julius Caesar into a star and a promise of immortality to Augustus. The *Metamorphoses* is strongly tinged with Alexandrine influence, being in fact a succession of epyllia in the Alexandrine manner. This work, which Ovid regards as his most serious claim to immortality, had not been finally revised at the time of his disgrace, and in his despair he burnt it; but other copies were in existence, and when he was at Tomi it was published at Rome by one of his friends. He often regrets that it had not received his final revision. The *Fasti* also was broken off by his exile, after the publication of the first six books, treating of the first six months of the year.

Banishment.—In A.D. 8 Ovid was ordered by Augustus into banishment; for this he assigns two causes, his *Ars amatoria* and an actual offence (*Trist.* ii. 207). It is natural that Augustus should have felt resentment against the *Ars,* because its doctrine was a direct challenge to his policy of moral reform. What the actual offence was is a secret which the poet leaves unrevealed; since his disgrace coincided with the banishment of Augustus' granddaughter, the younger Julia, on account of an intrigue with Silanus, it has been supposed that Ovid was concerned in abetting that intrigue, and that this constituted his unforgivable sin. But if Ovid had really assisted to bring about the moral scandal which befell the emperor's family, it is incredible that he could have dared to allude to it, as he does constantly, in his poems. This, and the fact that, even after Augustus' death, his successor Tiberius left Ovid unpardoned, makes it probable that the offence was political and specially displeasing to Tiberius and Livia because it somehow interfered with their dynastic policy. Ovid may have been implicated with those who were over-zealous in the interests of rival possible successors to the throne, either Agrippa Postumus, the grandson of Augustus, or Germanicus, the brilliant and popular nephew of Tiberius, with many of whose friends Ovid was associated. Ovid's banishment was the mildest possible (*relegatio*); it involved no deprivation of civic rights, and left him the possession of his property. He was ordered to remove to the half-Greek, half-barbaric town of Tomi, near the mouth of the Danube. For eight years he bore up in his dreary solitude, suffering from the unhealthiness of the climate and the constant alarm of inroads of barbarians.

The Epistle.—In the hope of procuring a remission of his punishment he wrote poetical complaints, first in the series of the five books of the *Tristia,* sent successively to Rome, addressed to friends whose names he suppresses; afterwards in a number of poetical epistles, the *Epistulae ex Ponto,* addressed by name to friends who were likely to have influence at court. He believed that Augustus had softened towards him before his death, but his successor Tiberius was inexorable to his appeals. His chief consolation was the exercise of his art, though as time goes on he is painfully conscious of failure in power. But although the works written by him in exile lack the finished art of his earlier writings, their personal interest is greater. They have, like the letters of Cicero to Atticus, the fascination exercised by all confessions; they are a sincere literary expression of the state of mind produced by a unique experience—that of a man, when well advanced in years but still retaining extraordinary sensibility to pleasure and pain, withdrawn from a brilliant social and intellectual position, and cast upon his own resources in a place and among people affording the dreariest contrast to the brightness of his previous life. The letters, which compose the *Tristia* and *Epistulae ex Ponto,* are addressed either to his wife, the emperor, or the general reader, or to his patrons and friends. To his patrons he writes in a vein of supplication, beseeching them to use their influence on his behalf. To his rather large circle of intimate acquaintances he writes in the language of familiarity, and often of affectionate regard; he seeks the sympathy of some, and speaks with bitterness of the coldness of others, and in three poems (*Trist.* iii., 11, iv. 9; v. 8) he complains of the relentless hostility of the enemy who had contributed to procure his exile, and whom he attacked in the *Ibis.* There is a note of true affection in the letter to the young lyric poetess Perilla, of whose genius and beauty he speaks with pride, and whose poetic talents he had fostered by friendly criticism (*Trist.* iii., 7). He was evidently a man of gentle and genial manners; and, as his active mind induced him to learn the language of the new people among whom he was thrown, his active interest in life enabled him to gain their regard and various marks of honour. One of his last acts was to revise the *Fasti,* and re-edit it with a dedication to Germanicus. The closing lines of the *Epistulae ex Ponto* sound like the despairing sigh of a drowning man who had long struggled alone with the waves:—

> Omnia perdidimus: tantummodo vita relicta est,
> Praebeat ut sensum materiamque mali.

Shortly after these words were written he died in his sixty-first year in A.D. 17.

Temperament.—The temperament of Ovid, as indicated in his writings, has more in common with the suppleness of the later Italian than with the strength and force of the ancient Roman. That stamp of her own character and understanding which Rome impressed on the genius of those other races which she incorporated with herself is fainter in Ovid than in any other great writer. He disclaims the manliness which was regarded as the birthright of the Roman. He is equally devoid of dignity in his brilliant prime, and in his later disgrace. His religion is devoid of reverence, his feeling for nature of depth, his loves of sincerity and, almost, even of passion.

These defects in strength and gravity show a corresponding result in Ovid's writings. Though possessing diligence, perseverance and literary ambition, he seems incapable of conceiving a great and serious whole. But with all the levity of his character he must have had qualities which made him, if not much esteemed, yet much liked in his own day, and which are apparent in the genial amiability of his writings. He claims for himself two virtues highly prized by the Romans, *fides* and *candor*—the qualities of social honour and kindly sincerity. There is no indication of anything base, ungenerous or morose in his relations to others. Literary *candor,* the generous appreciation of all sorts of excellence, he possesses in a remarkable degree. He heartily admires everything in literature, Greek or Roman, that had any merit. In him more than any of the Augustan poets we find words of admiration applied to the rude genius of Ennius and the majestic style of Accius. It is by him that

Lucretius is first named and his sublimity is first acknowledged. The image of Catullus that most haunts the imagination is that of the poet who died so early—

hedera iuvenalia cinctus
Tempora,

as he is represented by Ovid coming to meet the shade of the young Tibullus in Elysium. To his own contemporaries, known and unknown to fame, he is as liberal in his words of recognition. He enjoyed society too in a thoroughly amiable and unenvious spirit. In his exile he did retaliate on one enemy and persistent detractor in the *Ibis,* a poem written in imitation of a similar work by Callimachus; but the *Ibis* is not a satire, but an invective remarkable rather for recondite learning than for epigrammatic sting.

But Ovid's chief personal endowment was his vivacity, and his keen interest in and enjoyment of life. The age in which he lived was, as he tells us, that in which more than any other he would have wished to live. He is its most gifted representative, and by not rising above it he reflects it the more perfectly. The sympathy which he felt for the love adventures of his contemporaries, to which he probably owed his fall, quickened his creative power in the composition of the *Heroides* and the romantic tales of the *Metamorphoses.* None of the Roman poets can people a purely imaginary world with such spontaneous fertility of fancy as Ovid. In the power and range of imaginative vision he is surpassed by no ancient and by few modern poets. This power of vision is the counterpart of his lively sensuous nature. He has a keener eye for the apprehension of outward beauty, for the life and colour and forms of nature, than any Roman or perhaps than any Greek poet. This power, acting upon the wealth of his varied reading, gathered with eager curiosity and received into a singularly retentive mind, has enabled him to depict with consummate skill and sympathy legendary scenes of the most varied and picturesque beauty. If his tragedy, the *Medea,* highly praised by ancient critics, had been preserved, we should have been able to judge whether Roman art was capable of producing a great drama. In many of the *Heroides,* and in several speeches scattered through his works, he gives evidence of true dramatic creativeness. Among the poets of all times he can imagine a story with the most vivid inventiveness and tell it with the most unflagging animation. The faults of his verse and diction are those which arise from the vitality of his temperament—too facile a flow, too great exuberance of illustration. He has as little sense of the need of severe restraint in his art as in his life. He is not without mannerism, but he is quite unaffected, and, however far short he might fall of the highest excellence of verse or style, it was not possible for him to be rough or harsh, dull or obscure.

As regards the school of art to which he belongs, he may be described as the most brilliant representative of Roman Alexandrinism. The latter half of the Augustan age was, in its social and intellectual aspects, more like the Alexandrine age than any other era of antiquity. Poetry was the chief branch of literature, and the chief subjects of poetry were mythological tales, various phases of the passion of love, the popular aspects of science and some aspects of the beauty of nature. These two were the chief subjects of the later Augustan poetry. Ovid was the last of this class of writers.

Works.—His extant works fall naturally into three divisions, those of his youth, of middle life and of his later years. To the first of these divisions belong the amatory poems: (1) the three books of *Amores* (originally five, but reduced later to three) relating to his amours with his mistress Corinna; (2) the *Heroidum Epistolae;* (3) the *Medicamina formae,* a fragment of 100 lines on the use of cosmetics; (4) the three books of the *Ars amatoria;* (5) the *Remedia amoris* (one book), a kind of recantation of the *Ars amatoria.* To the second division belong (6) the fifteen books of the *Metamorphoses,* and (7) the six books of the *Fasti,* which was originally intended to be in twelve books, but which breaks off the account of the Roman calendar with the month of June. To the third division belong (8) the five books of the *Tristia,* (9) the *Ibis,* an invective against an enemy who had assisted to procure his fall, written in elegiac couplets probably soon after his exile; (10) the four books of *Epistulae ex Ponto.* Of these the first three were published soon after the *Tristia,* while the fourth book is a collection of scattered poems published by some friend soon after the author's death. The *Halieutica* is a didactic fragment in hexameters on the natural history of fishes, of doubtful genuineness, though it is certain that Ovid did begin such a work at the close of his life.[1]

In his extant works Ovid confined himself to two metres—the elegiac couplet and the hexameter. The great mass of his poetry is written in the first; while the *Metamorphoses* and the *Halieutica* are composed in the second. Of the elegiac couplet he is the acknowledged master. By fixing it into a uniform mould he brought it to its highest perfection; and the fact that the great mass of elegiac verse written subsequently has endeavoured merely to reproduce the echo of his rhythm is evidence of his pre-eminence. In the direct expression and illustration of feeling his elegiac metre has more ease, vivacity and sparkle than that of any of his predecessors, while he alone has communicated to it, without altering its essential characteristic of recurrent and regular pauses, a fluidity and rapidity of movement which make it an admirable vehicle for pathetic and picturesque narrative. It was impossible for him to give to the hexameter greater perfection, but he imparted to it also a new character, rapid, varied, animated in complete accord with the swift, versatile and fervid movement of his imagination. One other proof he gave of his irrepressible energy by composing during his exile a poem in the Getic (Gothic) language in praise of the imperial family, the loss of which, whatever it may have been to literature, is much to be regretted in the interests of philology.

It was in Ovid's writings that the world of romance and wonder created by Greek imagination was first revealed to modern times. His influence was first felt in the literature of the Italian Renaissance. But in the most creative periods of English literature he seems to have been read more than any other ancient poet, not even excepting Virgil, and it was on minds such as those of Marlowe, Spenser, Shakespeare, Milton and Dryden that he acted most powerfully. His influence is equally unmistakable during the classical era of Addison and Pope. The most successful Latin verse of modern times has been written in imitation of him; the faculty of literary composition and feeling for ancient Roman culture has been largely developed in the great schools of England and France by the writing of Ovidian elegiacs. His works afforded also abundant stimulus and materials to the great painters who flourished during and immediately after the Renaissance. Thus his first claim on the attention of modern readers is the influence which he has exercised on the development of literature and art; for this, if for no other reason, his works must always retain an importance second only to those of Virgil and Horace.

He is interesting further as the sole contemporary exponent of the last half of the Augustan age, the external aspects and inner spirit of which is known from the works, not of contemporary historians or prose-writers, but from its poets. The successive phases of Roman feeling and experience during this critical period are revealed in the poetry of Virgil, Horace and Ovid. Virgil throws an idealizing and religious halo around the hopes and aspirations of the nascent empire. Horace presents the most complete image of its manifold aspects, realistic, and ideal. Ovid reflects the life of the world of wealth and fashion under the influence of the new court, its material prosperity, its refinement, its frivolity and its adulation. He is the last true poet of the great age of Roman literature, which begins with Lucretius and closes with him. But the type of genius of which he affords the best example is more familiar in modern Italian than in ancient Roman literature. While the serious spirit of Lucretius and Virgil reappeared in Dante, it is Ariosto who may be said to reproduce the light-hearted gaiety and brilliant fancy of Ovid.

Bibliography.—The life of Ovid was first treated systematically by J. Masson, *Ovidii vita ordine chronologico digesta* (1780) (often reprinted, *e.g.*, in Burmann's edition). Modern literature on this subject will be found in Teuffel's *History of Roman Literature* (Eng. trans., ed. 2), § 247, and S. G. Owen's edition of *Tristia,* bk. i. The very numerous manuscripts of Ovid are chiefly of late date, 13th to

[1] Plin. *Hist. Nat.* xxxii. 152.

15th century. The earliest and best are: for the *Heroides*, a Paris ms. of the 9th, a Wolfenbüttel ms. of the 12th and an Eton fragmentary ms. of the 11th century (the *Epistula Sapphus*, found in no early ms., is best preserved in a 13th-century Frankfurt, and a 15th-century Harleian ms.); for the *Amores, Ars amatoria, Remedia amoris*, two Paris mss. of the 9th and 10th century respectively; for the *Medicamina formae*, a Florence ms. (Marcianus) of the 11th; for the *Metamorphoses* two Florence mss. (Marcianus and Laurentianus), and a Naples ms., all of the 11th century; for the *Fasti* two Vatican mss. of the 10th and 11th centuries; for the *Tristia*, a Florence ms. of the 11th; for the *Epistulae ex Ponto*, a fragmentary Wolfenbütten ms. of the 6th, and a Hamburg and two Munich mss. of the 12th; for the *Ibis* a Trinity college, Cambridge, ms. of the 12th; for the *Halieutica*, a Paris ms. of the 9th or 10th, and a Vienna ms. of the 9th century. Important for the text of the *Heroides* and *Metamorphoses* is the interesting paraphrase written in Greek by the monk Maximus Planudes in the latter half of the 13th century at Constantinople; that of the *Heroides* is printed in Palmer's edition of the *Heroides* (1898), that of the *Metamorphoses* in Lemaire's edition of *Ovid*, vol. v, edited by Boissonade. *See* also Gudeman, *De Heroidum Ovidii codice Planudeo* (Berlin, 1888).

Two indepedent *editiones principes* of Ovid were published contemporaneously in 1471, one at Rome, printed by Sweynheym and Pannartz, and one at Bologna by Balthasar Azoguidius: these present entirely different texts. *See* Owen's *Tristium libri*, v. p. lv. ff. The following are the most important editions: those marked with an asterisk have explanatory notes. Of the whole works: *Heinsius-Burmann (1727); *Amar-Lemaire (1820–24); Merkel-Ehwald (1874–88); Riese (1871–89); Postgate's *Corpus poetarum Latinorum*, by various editors (1894), reprinted separately (1898). Of separate works: *Amores*, *Némethy (1907); *Heroides*, Sedlmayer (critical) (1886); *Palmer (1898); *Epistula Sapphus* (separately), *De Vries (1888); *Ars amatoria*, *P. Brandt (1902); *Medicamina formae* (critical), Kunz (1881); *Metamorphoses*, *J. C. Jahn (1821); *Loers (1843); Korn (critical) (1880); *Haupt-Ehwald (1898–1903); Magnus (1914); *R. S. Lang (Oxford, 1927); *Fasti*, *Gierig (1812); Merkel (1841); (critical, with learned prolegomena on the sources, the Roman calendar, etc.); *Keightley (1848); *Paley (1854); *Peter (1889); *Cyril Bailey (Oxford, 1921); *Tristia*, *Loers (1839); S. G. Owen (1889) (critical), with notes and translation (1924); *Bk. i (1885), *Bk. iii (1889); *Cocchia (1900); *Epistulate ex Ponto*, Korn (1868) (critical), Bk. i; *Ellis (1881); *Némethy (1915); *Halieutica*, *Birt, *De Halieuticis Ovidio poetae falso adscriptis* (1878). There is a free verse translation of the *Amores* by Marlowe (*c.* 1600), and Dryden, with other hands under his supervision, published translation of various works between 1683 and 1717.

The special treatises on matters connected with Ovid are very numerous; a fairly complete list up to the time of publication is given in Owen's *Tristia* (critical edition), p. cviii ff.; in Teuffel's *History of Roman Literature* (trans. by Warr) and in Schanz's *Geschichte der römischen Litteratur;* and by Ehwald in the *Jahresbericht über die Fortschritte der classischen Altertumswissenschaft*, xxxi (1884) pp. 157 ff., lxxx (1894) pp. 1 ff., cix (1902) pp. 157 ff. The following deserve special mention. On the history of the text: Ehwald, *Ad historiam carminum Ovidianorum symbolae* (1889); *Kritische Beiträge zu Ovids Epistulae ex Ponto* (1896); Sedlmayer, *Prolegomena ad Heroidas* (1878); Gruppe, *Minos*, pp. 441 ff. (on interpolations). On style: Ovid's diction in connection with other writers—A. Zingerle, *Ovidius und sein Verhältnis zu den Vorgängern* (1869–71); *Martial's Ovid-Studien* (1877); W. Zingerle, *Untersuchungen zur Echtheitsfrage der Heroiden Ovids* (1878); W. Vollgraff, *Nikander und Ovid* (Groningen, 1909 foll.). Peculiarities of Ovid's style: van Iddekinge, *De Ovidii Romani iuris peritia* (1811); Washietl, *De similitudinibus imaginibusque Ovidianis* (1883); M'Crea, *On Ovid's Use of Colour and Colour Terms* (Classical studies in honour of H. Drisler) (1894). Metre: the structure of the Ovidian pentameter examined in relation to the textual criticism—Hilberg, *Gesetze der Wortstellung im Pentameter des Ovid* (1894) (fully reviewed by Ellis, *Classical Review*, ix 157). Literary appreciation: Sellar, *Roman Poets of the Augustan Age;* Lafaye, *Les Métamorphoses d'Ovid et leurs modèles grecs*. Ovid's relation to works of art: Wunderer, *Ovids Werke in ihrem Verhältnis zur antiken Kunst* (1890–91); Engelmann, *Bilder-Atlas zu Ovid's Metamorphosen* (1890). Cause of exile: the most interesting discussion is by Boissier in his *L'Opposition sous les Césars*. *See* also Nageotte, *Ovide, sa vie, ses oeuvres* (1872); Huber, *Die Ursachen der Verbannung des Ovid* (1888). Influence of Ovid upon Shakespeare: T. S. Baynes, *Shakespeare Studies* (1894); pp. 195 ff.; Constable, Shakespeare's "Venus und Adonis," in *Verhältnis zu Ovid's Metamorphosen* (1890). *See* also S. G. Owen, *Ovid and Romance* (1912).

(S. G. O.; X.)

OVIEDO, a maritime province of northern Spain, bounded on the north by the Bay of Biscay, east by Santander, south by León and west by Lugo. Pop. (1940) 836,642; area, 4,207 sq.mi. In popular speech Oviedo is often called by its ancient name of Asturias, which only ceased to be the official title of the province in 1833, when the Spanish system of local government was reorganized. An account of the physical features, history and inhabitants of this region is given under ASTURIAS. Oviedo is rich in forests, coal, streams and waterfalls, greatly contributing to its modern industrial development. The horses of Oviedo rank among the best in Spain. Wild deer, boars and bears were formerly common among the mountains; and the sea coasts, as well as the streams, abound with fish, including salmon and lampreys. The climate is mild and wet; the broken relief hinders cultivation. Although no trace exists of the gold for which Asturias was celebrated under its Roman rulers, Oviedo possesses valuable coal measures, which are worked at Langreo (mun. 43,797), Mieres (9,616, mun. 51,967), Siero (mun. 30,931) and elsewhere. The copper mines near Avilés (10,695, mun. 18,035) and Cangas de Onis (1,932, mun. 9,936) have lost their importance; but lead, magnesia, arsenic, cobalt, lapis lazuli, alum, antimony, jet, marble and rock crystal are found in various parts of the province, while amber and coral are gathered along the coast. There are manufactures of fine textiles, coarse cloth and ribbons in Salas (mun., 13,851), Piloña (mun., 16,948) and Avilés; of paper in Pianton; of porcelain and glass in Gijón (72,053, mun. 101,341), Avilés and Pola de Siero; of arms in Oviedo and Trubia; while foundries and works for the manufacture of agricultural implements, rails and pig iron are numerous. An important highway is the 16th century *Camino real*, or royal road, leading from Gijón to León and Madrid, which cost so much that the emperor Charles V inquired if it were paved with silver. A railway from Madrid to Oviedo, Gijón and Avilés runs through difficult parts of the Cantabrian chain.

Oviedo was the scene of serious uprisings in 1934, and of much fighting in the civil war of 1936–39.

OVIEDO, an episcopal city and capital of the Spanish province of Oviedo; 16 mi. S. of the Bay of Biscay, on the river Nalon, and on the León-Gijón, Oviedo-Trubia and Oviedo-Infiesto railways. Pop. (1940) 51,410 (mun., 82,548). Oviedo is built on a hill rising from a broad and picturesque valley, which is bounded on the north-west by the Sierra de Naranco. Oviedo, founded in the reign of Fruela (762), became the fixed residence of the kings of the Asturias in the time of Alphonso II, and continued to be so until about 924, when the advancing reconquest of Spain from the Moors led them to remove their capital to León. The university was founded by Philip III in 1604. The Gothic cathedral, founded in 1388, occupies the site of a chapel founded in the 8th century, of which only the Camara Santa remains. The Camara Santa (dating from 802) contains the famous *arca* of Oviedo, an 11th century Byzantine chest of cedar, overlaid with silver reliefs of Biblical scenes. In it are preserved two crosses dating from the 8th and 9th centuries. The cathedral library has some old mss., including a deed of gift made by Alpsonso II of Asturias in 812, and a collection of illuminated documents of the 12th century, the *Libro gótico*. Oviedo possesses historic churches, the ancient Santa María de Naranco, San Miguel de Lino, and the church of St. Julian or the Santullano, all of early date. Oviedo is an agricultural centre; other industries are marble quarrying, the manufacture of arms, fabrics, iron goods, leather and matches. In the 1936–39 rebellion, the Nationalists gained control of Oviedo early, but were then besieged by Asturian miners. A Nationalist relief expedition from Galicia lifted the siege Oct. 17, 1936.

OVIEDO Y VALDES, GONZALO FERNANDEZ DE (1478–1557), Spanish historian, was present at the surrender of Granada and saw Columbus previous to his voyage to America. He visited America himself on several occasions in an official capacity. Appointed historiographer of the Indies, Oviedo wrote —besides a romance of chivalry, *Don Claribalte* (1519)—two historical works: *Sumario de la natural y general historia de las Indias* (1526) and *La historia natural y general de las Indias, Islas e Tierra Firme del mar oceano* (1535–57). The latter work embodies a mass of curious information collected at first hand.

OVOLO, in architecture, a convex moulding (*q.v.*), whose profile approximates a quarter circle, a quarter ellipse or a similar curve; known commonly in the building trades as a quarter round. In its elliptical forms it is the characteristic echinus of the Greek Doric order and one of the two regular crowning and bed mouldings of the Ionic and its derivative orders. Its round form is used for the echinus of the Roman Doric order. In carpentry, at

a small scale, it is one of the most common mouldings used to cover a joint in a re-entrant angle, as between a base board and the floor, or between the side of a beam and the ceiling.

OWATONNA, a city of southeastern Minnesota, U.S.A., on the Straight river at an altitude of 1,154 ft., 70 mi. S. of Minneapolis; the county seat of Steele county. It is on federal highways 14, 65 and 218, and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Chicago and North Western, and the Rock Island railways and by bus lines. Pop. (1950) 10,191; (1940) 8,694. It is a trading centre of a farming and dairying region; its industries include co-operative creameries and manufacture of jewellery, tools, ventilating systems and farm implements. It is the home of the Owatonna State school for mentally retarded children (1886) and the town has eight schools; six public, including a high school, Pillsbury academy, a military school for boys, and St. Mary's parochial. Owatonna was settled about 1855, incorporated in 1865 and chartered as a city in 1875.

OWEGO, a village of southern New York, U.S.A., the county seat of Tioga county; on the north bank of the Susquehanna river, 21 mi. W. of Binghamton. It is served by the Erie, the Lackawanna and the Lehigh Valley railways. Pop. 1950 federal census, 5,352. Its factories produce shoes, folding furniture and other products. Owego occupies the site of an Indian village called Ah-wa-ga ("where the valley widens"), which was destroyed by Gen. Clinton in 1779. A white settlement was established in 1785, and the village was incorporated in 1827.

OWEN, JOHN [Ovenus or Audoenus] (*c.* 1560–1622), Welsh epigrammatist, born at Plas Dhu, Carnarvonshire, about 1560, was educated at Winchester school, and at New college, Oxford. He was a fellow of his college from 1584 to 1591, when he became a schoolmaster, first at Trelleck, near Monmouth, and then at Warwick. His perfect mastery of the Latin language brought him the name of "the British Martial."

Owen's *Epigrammata* are divided into twelve books, of which the first four were published in 1606, and the rest at four different times. Owen frequently adapts and alters to his own purpose the lines of his predecessors in Latin verse, and one such borrowing has become celebrated as a quotation, though few know where it is to be found. It is the first line of this epigram:—

> Tempora mutantur, nos et mutamur in illis:
> Quo modo? fit semper tempore peior homo.
> (Lib. I. ad Edoardum Noel, epig. 58.)

This first line is altered from an epigram by Matthew Borbonius, one of a series of mottoes for various emperors, this one being for Lothaire I.

> Omnia mutantur, nos et mutamur in illis:
> Illa vices quasdam res habet, illa vices.

There are editions of the *Epigrammata* by Elzevir and by Didot; the best is that edited by Renouard (2 vols., Paris, 1795). Translations into English, either in whole or in part, were made by Vicars (1619); by Pecke, in his *Parnassi Puerperium* (1659); and by Harvey in 1677, which is the most complete. La Torre, the Spanish epigrammatist, owed much to Owen, and translated his works into Spanish in 1674. French translations of the best of Owen's epigrams were published by A. L. Lebrun (1709) and by Kérivalant (1819).

OWEN, JOHN (1616–1683), English Nonconformist divine, was born at Stadham in Oxfordshire in 1616, and educated at Queen's college, Oxford. He was chaplain and tutor in the families, first of Sir Robert Dormer, and later of Lord Lovelace, but lost his place by siding with parliament in the Civil War. He then lived in Charterhouse yard, in London, and on April 29, 1646, preached, before the Long Parliament, a sermon which showed his tendency towards the tolerant Independent or Congregational system of Church government. He now became pastor at Coggeshall in Essex. He was chosen to preach to parliament on the day after the execution of Charles. Cromwell took him in 1649 as his chaplain to Ireland, where he regulated the affairs of Trinity college, and in 1650 to Scotland, making him chancellor of Oxford (1651), dean of Christ-church (1651–52) and vice-chancellor in 1652.

When Richard Cromwell succeeded his father, Owen lost his vice-chancellorship, and joined the Wallingford House party, throwing his influence on the side of a simple republic as against a protectorate. In March 1660 the Presbyterian party being uppermost, he was deprived of his deanery and returned to Stadham. Driven to London by the Conventicle and Five Mile Acts, he gathered a congregation there; at the revival of the Conventicle Acts in 1670 he drew up a protest to the House of Lords. After the Declaration of Indulgence (1672) he frequently preached in congregations of Independents and Presbyterians, and was in favour with Charles II. and James II. He died at Ealing on Aug. 24, 1683.

See Goold's edition of Owen's *Works* (1850–55); W. Orme, *Memoirs of Owen* (1820); and *The Golden Book of John Owen,* edited with a study of his life by James Moffat (1904).

OWEN, SIR RICHARD (1804–1892), English biologist, was born at Lancaster on July 20, 1804. In 1820 he was apprenticed to a local surgeon and apothecary, and in 1824 he proceeded as a medical student to the university of Edinburgh. After completing his medical course in St. Bartholomew's Hospital, London, where he came under the influence of the eminent surgeon, John Abernethy, he contemplated a professional career; but being induced by Abernethy to accept the position of assistant to William Clift, conservator of the museum of the Royal College of Surgeons, he devoted himself to the more congenial work of scientific research. He prepared an important series of catalogues of the Hunterian collection in the Royal College of Surgeons; and in the course of this work acquired the unrivalled knowledge of comparative anatomy which facilitated his researches on the remains of extinct animals. In 1836 he was appointed Hunterian professor in the Royal College of Surgeons, in 1849 he succeeded Clift as conservator, and in 1856 he became superintendent of the natural history department of the British Museum. He then devoted his energies to a scheme for a National Museum of Natural History, which eventually resulted in the removal of the natural history collections of the British Museum to a new building at South Kensington, the British Museum (Natural History). He retained office until the completion of this work in 1884, when he received the K.C.B., and thenceforward lived in retirement at Sheen Lodge, Richmond Park, until his death on Dec. 18, 1892.

While occupied with cataloguing the Hunterian collection, Owen seized every opportunity of dissecting fresh subjects. He had the privilege of investigating the animals which died in the Zoological Society's gardens; and when that society began to publish scientific proceedings in 1831, he was the most voluminous contributor of anatomical papers. His first notable publication, however, was his *Memoir on the Pearly Nautilus* (1832), which was soon recognized as a classic. Henceforth he continued to make important contributions to every department of comparative anatomy and zoology for over fifty years. Among Entozoa his most noteworthy discovery was that of *Trichina spiralis* (1835), the parasite infesting the muscles of man in the disease now termed trichinosis. (*See* also, however, the article on Paget, Sir James.) He also studied the Brachiopoda, Mollusca and he proposed the universally-accepted subdivision of the Cephalopoda into the two orders of Dibranchiata and Tetrabranchiata (1832). The problematical Arthropod *Limulus* was also the subject of a special memoir by him in 1873.

Owen's technical descriptions of the Vertebrata were still more numerous and extensive than those of the invertebrate animals. He not only studied existing forms, but also devoted great attention to the remains of extinct groups, and immediately followed Cuvier as a pioneer in vertebrate palaeontology. Early in his career he made exhaustive studies of teeth, both of existing and extinct animals, and published his work on *Odontography* (1840–1845). Most of his work on reptiles related to the skeletons of extinct forms, and his chief memoirs on British specimens were reprinted in a connected series in his *History of British Fossil Reptiles* (4 vols., 1849–1884). He also wrote widely on extinct birds. With regard to living mammals, the more striking of Owen's contributions relate to the monotremes, marsupials, and the anthropoid apes. Most of his writings on mammals, however, deal with extinct forms. Sir Thomas Mitchell's discovery of fossil bones in New South Wales provided material for the first of Owen's long series of papers on the extinct mammals of Australia,

which were eventually reprinted in book-form in 1877.

Owen's detailed memoirs and descriptions require laborious attention in reading, on account of their nomenclature and ambiguous modes of expression. But it must be remembered that he was a pioneer in concise anatomical nomenclature.

Besides the above mentioned works, Owen wrote: *Comparative Anatomy and Physiology of Vertebrates* (3 vols., 1866–68); *History of British Fossils, Mammals and Birds* (1844–46); *Monograph of the Fossil Mammalia of the Mesozoic Formations* (Paleont. Soc., 1871); *Antiquity of Man as deduced from the Discovery of a Human Skeleton* (1884). *Catalogue of the Fossil Reptilia of South Africa* (1876); *Archetype and Homologies of the Vertebrate Skeleton* (1848).

OWEN, ROBERT (1771–1858), British reformer and Socialist, was born at Newtown, Montgomeryshire, on May 14, 1771. His father had a small business in Newtown as saddler and ironmonger, and there young Owen received his school education, which terminated at the age of nine. After serving in a draper's shop for some years he settled in Manchester, where his success was rapid. When only 19 years of age he became manager of a cotton mill in which 500 people were employed, and by his administrative intelligence and energy soon made it one of the best establishments of the kind in Great Britain. In this factory Owen used the first bags of American sea-island cotton ever imported into the country; it was the first sea-island cotton from the Southern States. Owen also made improvements in the quality of the cotton spun; and indeed there is no reason to doubt that at this early age he was the first cotton-spinner in England, a position entirely due to his own capacity and knowledge of the trade. On becoming manager and partner in the Chorlton Twist Company at Manchester, Owen induced his partners to purchase the New Lanark mills, and after his marriage with Miss Dale, the daughter of the former proprietor, he settled there as manager and part-owner. Encouraged by his great success in Manchester, he had already formed the intention of conducting New Lanark on higher principles than the current commercial ones.

Connected with the mills were about 2,000 people, 500 of whom were children, brought, most of them, at the age of five or six from the poorhouses and charities of Edinburgh and Glasgow. The children especially had been well treated by Dale, but the general condition of the people was unsatisfactory. Crime and vice bred by demoralizing conditions were common; education and sanitation were alike neglected; and housing conditions were intolerable. It was this population which Owen set himself to elevate and ameliorate. He greatly improved their houses, and mainly by his personal influence trained them to habits of order, cleanliness and thrift. He opened a store, where the people could buy goods of the soundest quality at little more than cost price; and the sale of drink was placed under the strictest supervision. His greatest success, however, was in the education of the young, to which he devoted special attention. The first infant school in Great Britain was started, or rather evolved, by James Buchanan, with Owen's approval and support, at the New Lanark mills, and though earlier experiments had been made abroad, the new creation probably owed nothing to them.

In all these plans Owen obtained success. Though at first regarded with suspicion as a stranger, he soon won the confidence of his people. The mills continued to be a commercial success, but some of Owen's schemes involved considerable expense, which was displeasing to his partners. Tired at last of the restrictions imposed on him by men who wished to conduct the business on the ordinary lines, Owen formed a new firm, who, content with 5% of return for their capital, were ready to give freer scope to his philanthropy (1813). In this firm Jeremy Bentham and the well-known Quaker, William Allen, were partners. In the same year Owen published *A New View of Society, or Essays on the Principle of the Formation of the Human Character*, in which he expounded the principles on which his system of educational philanthropy was based. From an early age he had lost all belief in the prevailing forms of religion, and had thought out a creed for himself, which he considered an entirely new and original discovery. The chief points in this philosophy were that man's character is formed by circumstances over which he had no control and that he is not a proper subject either of praise or blame. These convictions led Owen to the conclusion that the great secret in the right formation of man's character is to place him under the proper influences from his earliest years. The irresponsibility of man and of the effect of early influences are the keynote of Owen's whole system of education and social amelioration.

Owen's new views theoretically belong to an old system of philosophy; his originality is to be found in his application of them. For the next few years Owen's work in New Lanark continued to have a national and even European significance. New Lanark itself became a much frequented place of pilgrimage for social reformers, statesmen, and royal personages, including Nicholas, afterwards emperor of Russia. According to the unanimous testimony of all who visited it, the results achieved by Owen were singularly good. The children brought up on his system, which included instruction through the eye as well as the ear, country walks, nature study, singing and dancing, were graceful, genial and unconstrained; health, plenty and contentment prevailed; and the business was a commercial success.

In 1815 Owen started, apparently single-handed, an agitation for factory reform. He drafted a bill to apply to all textile factories, prohibiting employment before ten years of age, and night-work before 18, limiting hours for those under 18 to 10½ a day, and providing for inspection. He failed to gain support from his fellow employers in Scotland, but found influential sympathizers in London, and the bill was introduced into parliament. There it was so emasculated that, after two sessions, Owen ceased to work for it, and disclaimed all responsibility for the mutilated measure passed in 1819. Hitherto Owen's work had been that of the practical reformer, whose distinction was the originality and ceaseless unselfishness of his methods. It was in 1817 that he first put forward the ideas which made him the forerunner of Socialism and Co-operation. These ideas were embodied in a report communicated to the committee of the House of Commons on the poor law.

The general misery and stagnation of trade consequent on the termination of the Napoleonic Wars was engrossing the attention of the country. After clearly tracing the special causes connected with the war which had led to such deplorable conditions, Owen pointed out that the permanent cause of distress was to be found in the competition of human labour with machinery, and that the only effective remedy was the united action of men, and the subordination of machinery. His proposals for the treatment of pauperism were based on these principles. He recommended that communities of about 1,200 persons each should be settled on quantities of land from 1,000 to 1,500 ac., all living in one large building in the form of a square, with public kitchen and mess-rooms. Each family should have its own private apartments, and the entire care of the children till the age of three, after which they should be brought up by the community, their parents having access to them at meals and all other proper times. These communities might be established by individuals, by parishes, by counties, or by the State; in every case there should be supervision by duly qualified persons. Work, and the enjoyment of its results, should be in common. The size of his community was no doubt suggested by his village of New Lanark; and he soon advocated such a scheme for the reorganization of society in general. In its fully developed form it was as follows. He desired that communities of from 500 to 3,000, mainly agricultural but possessing the best machinery, and being, as far as possible, self-contained, "should increase in number, unions of them federatively united shall be formed in circles of tens, hundreds and thousands," till they should embrace the whole world in a common interest.

His plans for the cure of pauperism were received at first with considerable favour. The *Times* and *Morning Post* and many of the leading men of the country countenanced them, one of his most steadfast friends being the duke of Kent, father of Queen Victoria. But at a large meeting in London, Owen declared his hostility to the received forms of religion. After this act of defiance his theories became suspect to the ruling classes though he did not lose all support from them. The radicals were intent

on political reform, which seemed to Owen on the wrong lines. His point of view was that machinery had come to stay and made social control of industry necessary to prevent the oppression and poverty of the workers. When he found there was no hope of Government action he turned to groups of sympathizers to carry out his plan of self-contained Communities. In 1825 he bought 30,000 ac. of land in Indiana, U.S.A., from the Rappite religious community, and re-named it New Harmony. There was no effective choice of colonists, and some necessary trades were inadequately represented. For a time the community life was well ordered and contented under Owen's practical guidance, and a constitution was adopted within a year, based on community of property and a representative government. But differences about the form of government and religion soon appeared, and all the numerous attempts at reconstruction failed to compose them, though there is a consensus of testimony to the admirable spirit which prevailed amidst all the dissensions. The community was wound up in 1828, and Owen lost £40,000—four-fifths of his fortune. The other chief Owenite Community experiments were at Queenwood, Hants (1839–45), in which Owen took part for three years; and Orbiston, near Glasgow (1825–28) and Ralahine in Ireland (1831–33), with neither of which he was directly concerned.

In 1828, after a long period of friction with William Allen and some of his other partners, Owen resigned all connection with New Lanark, and made his headquarters in London. Before he established New Harmony, U.S.A., he had begun to turn to the workers for support for his ideas. In his *Report to the County of Lanark* (a body of landowners) in 1820, he declared definitely that not reforms but a transformation of the social order was required. The appeal of such a doctrine to the workers is obvious. From 1820, his proposals for communities attracted the younger workers, brought up under the factory system, and between 1820 and 1830 numerous societies were formed and papers started to advocate his views. The growth of trade unionism and the emergence of a working-class point of view caused Owen's doctrines to be accepted as the expression of the workers' aspirations. When he returned to England in 1829 he found himself regarded as their leader. In the trade unions, Owenism stimulated the formation of self-governing workshops, and their need for a market led to the formation of "The Equitable Labour Exchange" in 1832.

Here Owen applied his principle that labour is the source of all wealth. Prices were calculated according to the cost of raw material and the time expended in making the article, and "Labour Notes" were used as the currency for dealings with the Exchange. After a few months of prosperity, rapacious demands from the landlord and the fact that the prices did not correspond with real exchange value brought the Labour Exchange to an end. The unprecedented growth of trade unions made it seem possible that the separate industries and eventually all industry might be organized by these bodies. Owen and his followers carried out an ardent propaganda all over the country, with the result that the new National Operative Builders Union turned itself into a Guild to carry on the building industry, and the Grand National Consolidated Trades Union was formed (1833–4). The enthusiasm and the numbers joining were remarkable, but the determined opposition of the employers and the severe repression by the Government and law courts, ended the movement in a few months. It was two generations before socialism, which was first popularly discussed at this time, again influenced trade unionism.

Throughout these years Owen's community ideas maintained their hold. From 1825 numerous co-operative societies for mutual trading were organized by Owen's followers, the profits being accumulated to provide funds for starting Owenite communities. Although the communities did not materialize, these short-lived co-operative stores showed that co-operative trading was possible and started the idea of using it as a means of changing the social system. They thus performed an important part in preparing the ground for the world-wide Consumers' Co-operative Movement which sprang from the Rochdale Pioneers Co-operative Society founded in 1844. These Pioneers were inspired by Owen's teaching, though their method of organizing production to supply their own needs developed on very different lines from his communities.

After 1834, Owen devoted himself to preaching his educational, moral, rationalist and marriage reform ideas. He formed the Association of All Classes of All Nations, and he was untiring in writing and speaking. His love of children and his great personal charm impressed all who came in contact with him up to the end of his life. At the age of 82, he became a spiritualist. He died on a visit to his birthplace, Newtown, on Nov. 17, 1858, his last act, the day before his death, being to draw up a plan for re-organizing the education of the town. He was buried at Newtown, and a memorial tablet was erected on his grave in 1902 by the Co-operative Union.

Robert Owen's four sons all became American citizens. The eldest, ROBERT DALE OWEN (1801–1877), sat in Congress (1844–47), and drafted the bill founding the Smithsonian Institution. In the Indiana House of Representatives, 1836–39 and 1851–52, and Constitutional Convention, 1850, he was instrumental in securing a married woman's property law, a common free school system, and more freedom in divorce. From 1853 to 1858 he was United States ambassador to Naples. He was a strong believer in spiritualism.

Of R. Owen's numerous works in exposition of his system, the most important are the *New View of Society;* the *Report* communicated to the Committee on the Poor Law; *The Report to the County of Lanark;* the *Book of the New Moral World;* and *Revolution in the Mind and Practice of the Human Race.* See *Life of Robert Owen written by himself* (1857), and *Threading my Way, Twenty-seven Years of Autobiography,* by R. D. O. (1874). There are also *Lives* of Owen by A. J. Booth (1869), W. L. Sargant (1860), Lloyd Jones (1889), F. A. Packard (Philadelphia, 1866), F. Podmore (1906) and G. D. H. Cole (with bibliography 1925). *See* also H. Simon, *Robert Owen: sein Leben und seine Bedeutung für die Gegenwart* (Jena, 1905); E. Dolléans, *Robert Owen* (Paris, 1905); G. J. Holyoake, *History of Co-operation in England* (1906); Leonard Woolf, *Co-operation and the Future of Industry* (1919) and the article COMMUNISM.

OWENSBORO, a city of Kentucky, U.S., the county seat of Daviess county; on the Ohio river and federal highway 60, 114 mi. S.W. of Louisville. It is served by the Illinois Central and Louisville and Nashville railroads, motorbus lines and river steamers.

There is a vehicular bridge across the Ohio river from the centre of the city. Pop. (1950) 33,651; (1940) 30,245; (1920) 17,424, by the federal census. It is an important market for tobacco as well as corn, wheat, potatoes, dairy and poultry products and livestock. Its manufactures are varied and important. It is the centre of a gas and oil field.

The city has a commission form of government. The site of Owensboro was known to the early boatmen of the Ohio as Yellow Banks. The first cabin was built in 1799. The town was laid out for the county seat in 1815 and named Rossborough.

In 1817 it was incorporated under the present name, after Col. Abraham Owen (1769–1811), but the old name of Yellow Banks clung to it until the '40s. It was chartered as a city in 1866.

OWEN SOUND, a city and port of entry in Ontario, Can., and capital of Grey county, situated 120 mi. N.W. of Toronto, on Sydenham river and Georgian bay. Pop. (1951) 16,204. It is the terminus of branches of the Canadian Pacific and Canadian National railways, and of the Canadian Pacific and other steamship lines plying to ports on Lakes Huron and Superior. The sound is 12 mi. long and 5 mi. wide; the port harbour is one of the best on Lake Huron and navigable by lake vessels of the largest size.

It is a flourishing town, containing shipbuilding yards and manufactories of mill machinery, agricultural implements, furniture and sewing machines. There are flour mills, sawmills and tanneries. Large terminal grain elevators facilitate transshipment of western Canada grain from steamer to rail.

OWL, the general name for the nocturnal birds of prey. The owls form a very natural assemblage, and this suborder, *Striges,* is not closely related to the hawks and eagles. Owls vary in length from 5 in. in *Glaucidium cobanense* to more than 2 ft. The plumage is very soft, rendering the flight noiseless. On each side of the base of the beak are several rows of small, curved, stiff-shafted feathers, which form a ruff to support the long feathers of the

"disc" or space around the eyes. The ears are large, with well-developed, and often asymmetrical folds of skin, so that the right and left ears may be differently shaped. Many species of owl show two phases of coloration—one in which the brown inclines to red, the other in which it inclines to gray. The outer toes of all owls are reversible. Unlike most birds, owls incubate from the laying of the first egg.

The type of the family *Aluconidae* is the tawny owl (*Strix aluca*), found throughout Europe and in Asia Minor, Palestine and Barbary. A woodland bird, it feeds largely on rats, mice, voles and shrews. Allied species are found in America, northern Europe and Asia. The remaining owls form the family *Strigidae*.

SPOTTED OWL (SYRNIUM OCCIDENTALE) OF WESTERN U.S.

The eagle owl, *Bubo ignavus*, ranges over most of Europe and Asia north of the Himalayas. The allied *B. virginianus* extends over all North America. They are sombre-coloured birds and among the largest species. Equally large is the snowy owl (*Nyctea scandiaca*), a circumpolar species with white plumage. In winter it migrates southward. The long- and short-eared owls (*Asio otus* and *A. accipitrinus*) are common to the northern parts of Europe and America; the latter, often seen abroad in the daytime, preferring open country, also extending into North Africa, all South America and Hawaii. The long-eared owl keeps to woods. Both possess erectile tufts on the side of the head. *Speotyto cunicularia* of America lives in burrows, frequently sharing those of the prairie dog and biscacha. The bird of Pallas Athene is *Athene noctua*, the little owl of Europe, which was introduced into Great Britain, where it spread rapidly. *A. brama* replaces it in India. The American screech owl (*Megascops asio*), in its numerous varieties, is found practically throughout North America except at the far north. It varies much in colour and size. It can be distinguished from other owls at night by its peculiar screams, snarls and hisses.

OWOSSO, a city of Shiawassee county, Mich., U.S., 33 mi. N.E. of Lansing, on the Shiawassee river. It was the home of Thomas E. Dewey and J. O. Curwood. It is served by the Ann Arbor, the Grand Trunk and the Michigan Central railways and by bus lines. The population was 15,948 in 1950 and was 14,424 in 1940. It is division point for the Ann Arbor railroad, which has repair shops there, and Indian Trails bus lines. It is the trade centre of a rich agricultural county and has many diversified industries. Industries include electric motors, batteries, sandpaper, screen doors, snow shovels and furniture. The city was founded in 1833 and chartered in 1859.

OX, strictly speaking, the Saxon name for the males of domesticated cattle (*Bos taurus*), but in a zoological sense employed so as to include not only the extinct wild ox of Europe but likewise bovine animals of every description; that is to say, true oxen, bison and buffaloes. The characteristics of the subfamily Bovinae, or typical section of the family Bovidae, are given in the article BOVIDAE; for the systematic position of that family *see* PECORA. For the typical oxen, as represented by the existing domesticated breeds, *see* CATTLE.

OXALIC ACID, the simplest dibasic organic acid. It is one of the strongest organic acids. Its formula is $(COOH)_2$, or, in its usual form of crystalline hydrate, $(COOH)_2.2H_2O$. Its occurrence in wood sorrel (*Oxalis acetosella*, hence the name) and in sour dock (*Rumex acetosa*) in the form of its potassium salt was known at the beginning of the 17th century. Karl W. Scheele in 1776 prepared the acid by oxidizing sugar with nitric acid and showed this acid to be identical with the one derived from sorrel. The existence of oxalates in nature is widespread in both plant and animal kingdoms.

There are four technical methods for the manufacture of oxalic acid: (1) Synthetic sodium formate is heated to 360° C. in the presence of an alkali catalyst to yield hydrogen and sodium oxalate, from which oxalic acid is obtained. (2) Carbohydrates, such as sugar, starch or cellulose, are oxidized with concentrated nitric acid in the presence of a vanadium catalyst to give oxalic acid. The oxides of nitrogen are recovered and reoxidized. (3) Wood waste, such as sawdust, is treated with fused sodium hydroxide to give sodium oxalate. This process became obsolete at the end of the 19th century, but in 1942 a procedure for carrying out this reaction continuously, thereby lowering the cost, was described. (4) Fermentation of sugar solutions by moulds was later developed.

Oxalic acid crystallizes from water as a dihydrate in monoclinic prisms melting at 101.5° C. Heated at 100° C. it readily loses its water of crystallization. The anhydrous acid begins to sublime below 100° C. and sublimes rapidly above 125° C. The anhydrous acid may be recrystallized from glacial acetic acid and melts at 189.5° C. It has been used as a condensing agent. When heated more strongly, oxalic acid decomposes into carbon dioxide, carbon monoxide and water. The decomposition to carbon dioxide and formic acid is an intermediate stage in this reaction. Dehydrating agents such as sulphuric acid accelerate the thermal decomposition of oxalic acid. Oxalic acid heated with glycerine at 100° C. gives formic acid and carbon dioxide. At higher temperatures allyl alcohol is formed. Electrolytic reduction of oxalic acid at lead or mercury cathodes yields glycollic acid. At low temperatures glyoxylic acid may be obtained as an intermediate stage. Permanganates in acid solution oxidize oxalic acid to carbon dioxide and water. The reaction is autocatalytic. It is of great importance in analytical chemistry. In the presence of uranyl salts, oxalic acid undergoes photochemical decomposition. This reaction has found application in actinometry. Oxalic acid may be characterized by the following spot test: a fragment, melted with a little diphenylamine in a micro test tube, is heated over a free flame. The melt is then dissolved in a drop of alcohol. Formation of aniline blue shows the presence of an oxalate. Deutero-oxalic acid and its deuterate have been prepared and studied.

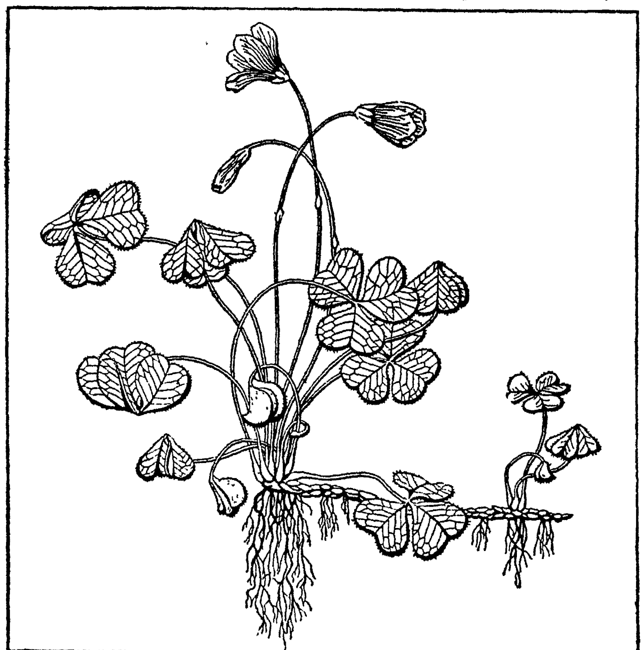
Oxalic acid is widely used as a laundry sour, where, in addition to neutralizing alkalinity, it is unusually effective in removing rust and ink stains since it forms a complex ferrioxalate ion with iron. Oxalic acid together with a small amount of added corrosion inhibitor is the chief constituent of the many automobile radiator scale removers now on the market. These two uses consume a large part of the oxalic acid of commerce. It is also employed as an electrolyte in the anodic oxidation of aluminum, as a bleaching agent for straw, cork and rosin, as a wash for anthracite coal which has been too long in storage and as a precipitant for rare earths. It is often used where an acid in solid, water-soluble, nonhygroscopic form is desired, as in printing of cloth, photography, etc. The sodium salt is used in pyrotechnics, as an anti-flash agent in artillery ammunition and in chrome tanning to increase the amount of chromium taken up by the hide. The iron salt is used in the manufacture of blueprint paper, the tin and antimonyl salts in printing and dyeing.

Oxalic acid is poisonous. The antidotes for oxalic acid poisoning are milk of lime, chalk, whiting or even wall plaster, followed by evacuation brought about by an enema or castor oil. Only the salts of the alkali metals are soluble in water. Beside the ordinary acid and neutral salts, a series of salts called tetraoxalates is known, these being salts containing one molecule of acid salt, in combination with one molecule of acid; one of the most common is "salt of sorrel," $KHC_2O_4.H_2C_2O_4.2H_2O$. The oxalates are readily decomposed when heated, leaving a residue of carbonate, or oxide of the metal. The silver salt decomposes with explosive violence, leaving a residue of the metal.

Potassium ferrous oxalate, $FeK_2(C_2O_4)_2.H_2O$, is a strong reducing agent and is used as a photographic developer. Potassium ferric oxalate, $FeK_3(C_2O_4)_3$, is used in the preparation of platinotypes, owing to the fact that its solution is rapidly decomposed by sunlight, $2FeK_3(C_2O_4)_3 = 2FeK_2(C_2O_4)_2 + K_2C_2O_4 + 2CO_2$. Ethyl oxalate, $(CO.OC_2H_5)_2$, prepared by boiling anhydrous oxalic acid with absolute alcohol, is a colourless liquid which boils at 186° C. Methyl oxalate, $(CO.OCH_3)_2$, which is prepared in a similar manner, is a solid melting at 54° C. It is used in the preparation of pure methyl alcohol. Oxalyl chloride, a liquid boiling at 64° C. (m.p. −12° C.), has been obtained by the action of phosphorus pentachloride on anhydrous oxalic acid. Oxamic acid,

$HO_2C.CONH_2$, is obtained by heating acid ammonium oxalate or by boiling oxamide with ammonia; it is among the products produced when amino acids are oxidized with potassium permanganate. It is a crystalline powder difficultly soluble in water and melting at 210° C. (with decomposition). Its ethyl ester, known as oxamethane, crystallizes in rhombic plates which melt at 114–115° C. Oxamide, $(CONH_2)_2$, is best prepared by the action of ammonia on the esters of oxalic acid. It is also obtained by the action of hydrogen peroxide on hydrocyanic acid, or of manganese dioxide and sulphuric acid on potassium cyanide. It is a white crystalline powder which is almost insoluble in cold water. It melts at 417–419° C. (with decomposition) when heated in a sealed tube (A. Michael, 1895). When heated with phosphorus pentoxide it yields cyanogen. It is readily hydrolysed by hot solutions of the caustic alkalies. Substituted oxamides are produced by the action of primary amines on ethyl oxalate.

OXALIS, a large genus of small herbaceous plants, comprising, with a few small allied genera, the family Oxalidaceae. The name is derived from Gr. ὀξύς, acid, the plants being highly acid to the taste. The genus contains about 800 species, chiefly South African and tropical and South American. It is represented in Great Britain and eastern North America by the wood-sorrel (*O. acetosella*), a small, stemless plant with radical, trefoil-like leaves growing from a creeping, scaly rootstock, and the flowers borne singly on an axillary stalk; the flowers are regular with five sepals, five obovate, white, purple-veined, free petals, ten stamens and a central five-lobed, five-celled ovary with five free styles. The fruit is a capsule, splitting by valves; the seeds have a fleshy coat, which curls back elastically, ejecting the true seed. The leaves, as in the other species of the genus, show a "sleep-movement," becoming pendulous at night. Besides the wood-sorrel, some 20 other species occur in North America, among which are the yellow wood-sorrel (*O. stricta*), of the eastern United States and Canada, with yellow flowers; the violet wood-sorrel (*O. violacea*), of the eastern United States, with rose-purple flowers; the



WOOD SORREL (OXALIS ACETOSELLA)

redwood wood-sorrel (*O. oregana*), of the coast redwood belt from California to Oregon with pink to white flowers and *O. cernua,* known as Bermuda buttercups, with showy yellow flowers, native to South Africa and naturalized in Florida and the Bermudas. *Oxalis crenata,* the oca of South America, is a tuberous-rooted half-hardy perennial, native of Peru. Its tubers are comparatively small, and somewhat acid; but if they be exposed in the sun from 6 to 10 days they become sweet and floury. *Oxalis deppei,* a bulbous perennial of Mexico, has scaly bulbs, from which are produced fleshy, tapering, white, semi-transparent, edible roots, about 4 in. in length and 3 to 4 in. in diameter.

Various species are in cultivation as basket plants for window gardens, border plants and hot house ornamentals. *See* R. Knuth, "Oxalidaceae," *Pflanzenreich* 95 (iv, 130): 1–481, fig. 1–28 (1930).

OXENSTJERNA, COUNT AXEL GUSTAFSSON (1583–1654), chancellor of Sweden, was born at Fånö, and was educated with his brothers at the universities of Rostock, Jena and Wittenberg. On returning home in 1603 he was appointed *kammerjunker* to King Charles IX. In 1606 he was entrusted with his first diplomatic mission, to Mecklenburg, was appointed a senator during his absence, and henceforth became one of the king's most trusted servants. In 1610 he was sent to Copenhagen to prevent a war with Denmark. This unsuccessful embassy marks the beginning of Oxenstjerna's long diplomatic struggle with Sweden's traditional rival in the north. Oxenstjerna was appointed a member of Gustavus Adolphus's council of regency. High aristocrat as he was, he would at first willingly have limited the royal power. An oligarchy guiding a limited monarchy was his ideal government, but the genius of the young king was not to be fettered. On Jan. 6, 1612, he was appointed chancellor. His controlling, organizing hand was speedily felt in every branch of the administration. For his services as first Swedish plenipotentiary at the Peace of Knäred, 1613, he was richly rewarded.

During the frequent absences of Gustavus in Livonia and Finland (1614–1616) Oxenstjerna acted as his vice-regent. It was his principal duty during the king's Russian and Polish wars to supply the armies and the fleets with everything necessary, including men and money. In 1622 he accompanied Gustavus to Livonia, where Oxenstjerna was appointed governor-general and commandant of Riga. His services in Livonia were rewarded with four castles and the whole bishopric of Wenden. He was entrusted with the peace negotiations which led to the truce with Poland in 1623, and succeeded, by skilful diplomacy, in averting a threatened rupture with Denmark in 1624. On Oct. 7, 1626, he was appointed governor-general of the newly-acquired Prussian province. In 1629 he concluded the truce of Altmark with Poland. In 1628 he had arranged with Denmark a joint occupation of Stralsund, to prevent the fortress from falling into the hands of the Imperialists. After the battle of Breitenfeld (Sept. 7, 1631) he was summoned to assist the king with his counsels and co-operation in Germany. During the king's absence in Franconia and Bavaria in 1632 he was appointed *legatus* in the Rhine lands, with plenipotentiary authority over all the German generals and princes in the Swedish service.

Although he never fought a battle, Oxenstjerna was a born strategist. His military capacity was strikingly demonstrated by the skill with which he conducted large reinforcements to Gustavus through the heart of Germany in the summer of 1632. But it was only after the death of the king at Lützen that Oxenstjerna's true greatness came to light. He inspired the despairing Protestants both in Germany and Sweden with fresh hopes. He reorganized the government both at home and abroad. He united the estates of the four upper circles into a fresh league against the common foe (1634), in spite of the envious and foolish opposition of Saxony. By the patent of Jan. 12, 1633, he had already been appointed legate plenipotentiary of Sweden in Germany with absolute control over all the territory already won by the Swedish arms. No Swedish subject, either before or after, ever held such an unrestricted and far-reaching authority. Richelieu himself declared that the Swedish chancellor was "an inexhaustible source of well-matured counsels."

Less original but more sagacious than the king, he had a firmer grasp of the realities of the situation. Gustavus would not only have aggrandized Sweden, he would have transformed the German empire. Oxenstjerna wisely abandoned these vaulting ambitions. All his efforts were directed towards procuring for the Swedish crown adequate compensation for its sacrifices. Simple to austerity in his own tastes, he nevertheless recognized the political necessity of impressing his allies and confederates by an almost regal show of dignity; and at the abortive congress of Frankfort-on-Main (March 1634), held for the purpose of uniting all the German Protestants, Oxenstjerna appeared in a carriage drawn

by six horses, with German princes attending him on foot. But from first to last his policy suffered from the slenderness of Sweden's material resources, a cardinal defect which all his craft and tact could not altogether conceal from the vigilance of her enemies. The success of his system postulated an uninterrupted series of triumphs, whereas a single reverse was likely to be fatal to it. Thus the frightful disaster of Nördlingen (Sept. 6th, 1634; *see* SWEDEN: *History*) compelled him to solicit direct assistance from France. But he refused at the conference of Compiègne (1635) to bind his hands in the future for the sake of some slight present relief. In 1636, however, he concluded a fresh subsidy-treaty with France at Wismar.

The same year he returned to Sweden and took his seat in the Regency. For the next nine years his voice, especially as regarded foreign affairs, was omnipotent in the council of state. He drew up beforehand the plan of the Danish War of 1643–1645, so brilliantly executed by Lennart Torstensson, and saw Denmark crippled by the Peace of Brömsebro (1645). His later years were embittered by the jealousy of the young Queen Christina, who thwarted the old statesman in every direction. He always attributed the exiguity of Sweden's gains by the Peace of Osnabrück to Christina's undue interference. Oxenstjerna was opposed at first to the abdication of Christina, because he feared mischief to Sweden from her appointed successor, Charles Gustavus. The extraordinary consideration shown to him by the new king ultimately, however, reconciled him to the change. He died at Stockholm on Aug. 28, 1654.

OXENSTJERNA, COUNT BENGT OR BENEDICT GABRIELSSON (1623–1702) was the son of Axel Oxenstjerna's half-brother, Gabriel Bengtsson (1586–1656). After a careful education he began his diplomatic career at the great peace congress of Osnabrück. During his stay in Germany he made the acquaintance of the count palatine, Charles Gustavus, afterwards Charles X., whose confidence he completely won. Two years after the king's accession (1654), Oxenstjerna was sent to represent Sweden at the *Kreistag* of Lower Saxony In 1655 he accompanied Charles to Poland and was made governor of the conquered provinces of Kulm, Kujavia, Masovia and Great Poland. The firmness and humanity which he displayed in this new capacity induced the German portion of them, notably the city of Thorn, to side with the Swedes against the Poles. During Charles's absence in Denmark (1657), Oxenstjerna, in the most desperate circumstances, tenaciously defended Thorn for ten months; the terms of capitulation were made the basis of the subsequent peace negotiations at Oliva. During the domination of Magnus de la Gardie he played but a subordinate part in affairs. From 1662 to 1666 he was governor-general of Livonia. In 1674 he was sent to Vienna to try and prevent the threatened outbreak of war between France and the empire, and he was one of the Swedish envoys to the Congress of Nijmwegen (1676). From 1680 to 1697 he conducted the foreign relations of Sweden.

His leading political principles were friendship with the maritime powers (Great Britain and Holland) and the emperor, and a close anti-Danish alliance with the house of Holstein. Charles XI. appointed Oxenstjerna one of the regents during the minority of Charles XII. The martial proclivities of the new king filled the prudent old chancellor with alarm and anxiety. He advised Charles in vain to accept the terms of peace offered by the first anti-Swedish coalition. Oxenstjerna has been described as "a shrewd and subtle little man, of gentle disposition, but remarkable for his firmness and tenacity of character."

OXFORD, EARLS OF, an English title held successively by the families of Vere and Harley. The three most important earls of the Vere line are noticed separately below. The Veres held the earldom from 1142 until March 1703, when it became extinct on the death of Aubrey de Vere, the 20th earl. In 1711 the English statesman Robert Harley was created earl of Oxford (*q.v.*); but the title became extinct in this family on the death of the 6th earl in 1853. It was revived in favour of H. H. Asquith who became earl of Oxford and Asquith (*q.v.*).

OXFORD, EDWARD DE VERE, 17TH EARL (in the Vere line) OF (1550–1604), son of John de Vere, the 16th earl, was born on April 12, 1550. He studied at Queen's and St. John's Colleges, Cambridge. He was known as Lord Bolebec or Bulbeck until he succeeded in 1562 to the earldom and to the hereditary dignity of great chamberlain of England. As a royal ward the boy lived under the care of Lord Burghley, who in 1571 gave him his eldest daughter, Anne, in marriage. Oxford wished for a military or a naval command, but Burghley hoped that he would win a high position at court. His accomplishments secured Elizabeth's favour, but he offended her by going to Flanders without her consent in 1574, and more seriously in 1582 by a duel with one of her gentlemen, Thomas Knyvet. In 1579 he insulted Sir Philip Sidney on the tennis-court at Whitehall.

Sidney challenged Oxford, but the queen forbade him to fight, and required him to apologize on the ground of their difference of rank. On Sidney's refusal and consequent disgrace Oxford is said to have schemed to murder him. The earl sat on the special commission (1586) for the trial of Mary queen of Scots; he took part in the trials of Philip Howard, earl of Arundel, for high treason in 1589, and of Essex and Southampton in 1601. In 1575 he brought back from Italy various inventions for the toilet, and his estate was rapidly dissipated in satisfying his extravagant whims. His first wife died in 1588, and from that time Burghley withdrew his support, Oxford being reduced to the necessity of seeking help among the poor men of letters whom he had befriended. He was a lyric poet of no small merit. His fortunes were partially retrieved on his second marriage with Elizabeth Trentham, by whom he had a son, Henry de Vere, 18th earl of Oxford (1593–1625). He died at Newington, near London, on June 24, 1604.

His poems, from various anthologies—the *Paradise of Dainty Devices, England's Parnassus, Phoenix Nest, England's Helicon*—and elsewhere, were collected by Dr. A. B. Grosart in vol. iv of the Fuller Worthies Library (1876).

OXFORD, JOHN DE VERE, 13TH EARL OF (1443–1513), was second son of John, the 12th earl, a prominent Lancastrian, who, with his eldest son Aubrey de Vere, was executed in February 1462. John de Vere the younger was himself attainted, but two years later was restored as 13th earl. But his loyalty was suspected, and for a short time in 1468 he was in the Tower. He sided with Warwick, the king-maker, in 1469, accompanied him in his exile next year, and assisted in the Lancastrian restoration of 1470–1471. As constable he tried John Tiptoft, earl of Worcester, who had condemned his father nine years before. At the battle of Barnet, Oxford was victorious in command of the Lancastrian right, but was ultimately defeated and escaped to France. In 1473 he organized a Lancastrian expedition, which, after an attempted landing in Essex, seized St. Michael's Mount in Cornwall. After a four months' siege Oxford was forced to surrender in Feb. 1474. He was sent to Hammes near Calais, whence, ten years later, in Aug. 1484, he escaped and joined Henry Tudor in Brittany. He fought for Henry at Bosworth, and was rewarded by restoration to his title, estates and hereditary office of Lord Chamberlain. At Stoke on June 16, 1486, he led the van of the royal army. In 1492 he commanded the expedition to Flanders, and in 1497 was foremost in the defeat of the Cornish rebels on Blackheath. Oxford was high steward at the trial of the earl of Warwick, and one of the commissioners for the trial of Sir James Tyrell and others in May 1502. He died March 10, 1513.

OXFORD, ROBERT DE VERE, 9th Earl of (1362–1392), English courtier, was the only son of Thomas de Vere, 8th earl of Oxford, and Maud de Ufford, a descendant of King Henry III. He became 9th earl of Oxford in 1371, and married Philippa (d.

1412), daughter of his guardian Ingelram de Couci, earl of Bedford, a son-in-law of Edward III. Already hereditary great chamberlain of England, Oxford was made under Richard II. a member of the privy council and a Knight of the Garter; while castles and lands were bestowed upon him, and he was constantly in the company of the young king. In 1385 Richard sent him to govern Ireland, but although preparations were made for his journey he did not leave England. The king's partiality for Oxford was one of the causes of the dissatisfaction of the barons. Oxford also made powerful enemies by divorcing his wife, Philippa, and by marrying a Bohemian lady.

The king, however, indifferent to the gathering storm, created Vere duke of Ireland in Oct. 1386, and gave him still more powers in that country. Richard was deprived of his authority for a short time, and Vere was ordered in vain to proceed to Ireland. He was then accused by the king's uncle Thomas of Woodstock, duke of Gloucester, and his supporters in 1387; and rushing into the north of England he gathered an army to defend his royal master and himself. At Radcot bridge in Oxfordshire, however, his men fled before Gloucester's troops and Oxford himself escaped in disguise to the Netherlands. In the parliament of 1388 he was found guilty of treason and condemned to death, but as he remained abroad the sentence was never carried out. With another exile, Michael de la Pole, duke of Suffolk, he lived in Paris until after the treaty between England and France in 1389, when he took refuge at Louvain. He was killed by a boar whilst hunting, and left no children.

OXFORD, ROBERT HARLEY, 1st Earl of (1661–1724), English statesman, commonly known by his surname of Harley, eldest son of Sir Edward Harley (1624–1700), a Herefordshire land-owner, was born in Bow street, London, on Dec. 5, 1661. His school days were passed at Shilton, near Burford, in Oxfordshire, in a small school which produced at the same time a lord high treasurer (Harley), a lord high chancellor (Simon Harcourt) and a lord chief justice of the common pleas (Thomas Trevor). The principles of Whiggism and Nonconformity were instilled into his mind at an early age, and if he changed the politics of his ancestors he never formally abandoned their religious opinions. At the Revolution of 1688 Sir Edward and his son raised a troop of horse in support of the cause of William III., and took possession of the city of Worcester in his interest. Young Harley then (1689) entered parliament for the "pocket" borough of Tregony. Later he sat for New Radnor, a seat which he held until his elevation to the peerage in 1711.

From the first Harley gave great attention to the conduct of public business, and from the general election of Feb. 1701 until the dissolution of 1705 he held the office of speaker. In 1704 he became a principal secretary of State for the northern department. In 1703 Harley first made use of Defoe's talents as a political writer, and this alliance with the press proved so successful that he afterwards called the genius of Swift to his aid in many pamphlets against his political opponents. While he was secretary of State the union with Scotland was effected. At the time of his appointment as secretary of State Harley had given no outward sign of dissatisfaction with the Whigs, and it was mainly through Marlborough's good opinion of his abilities that he was admitted to the ministry. For some time Harley acted loyally with his colleagues. But in the summer of 1707 it became evident to Godolphin that some secret influence behind the throne was shaking the confidence of the queen in her ministers. Abigail Hill, who was secure in the queen's confidence, was Harley's cousin, and his instrument in influencing the queen against her ministers. These bided their time, until an opportunity for Harley's overthrow was provided. A clerk in Harley's department divulged the contents of secret documents in his office, which should have been inaccessible to anyone but the chief, and the queen was thereupon informed that Godolphin and Marlborough could no longer serve in concert with him. They did not attend her next council (Feb. 8, 1708), and the queen found herself forced (Feb. 11) to accept the resignations of both Harley and St. John.

Harley went out of office, but his cousin, who had now become Mrs. Masham, remained at court to further his interests. The cost of the protracted war with France, and the danger to the national church, the chief proof of which lay in the prosecution of Sacheverell, were the weapons which he used to influence the masses of the people. Marlborough himself could not be dispensed with, but his relations were dismissed from their posts in turn. When the greatest of these, Lord Godolphin, was ejected from office, five commissioners to the treasury were appointed (Aug. 10, 1710), and among them figured Harley as chancellor of the exchequer. It was the aim of the new chancellor to frame an administration from the moderate members of both parties, and to adopt with but slight changes the policy of his predecessors; but he failed. By an unexpected event, his popularity was restored at a bound. A French refugee, the ex-abbé de la Bourlie (better known by the name of the marquis de Guiscard), was being examined before the privy council on a charge of treachery, when he stabbed Harley in the breast with a penknife (March 8, 1711). On May 23, 1711, the minister became Baron Harley of Wigmore and earl of Oxford and Mortimer; and immediately afterwards lord treasurer and a Knight of the Garter.

Oxford rearranged the nation's finances, and supplied resources for carrying on the campaign, though his emissaries were in communication with the French king, and were settling the terms of a peace independently of England's allies. After many weeks of vacillation and intrigue, the preliminary peace was signed, and in spite of the opposition of the Whig majority in the Upper House, which was met by the creation of 12 new peers, the treaty of Utrecht was concluded (March 31, 1713). While these negotiations were under discussion the friendship between Oxford and St. John, who had become secretary of State in Sept. 1710, was fast changing into hatred. The latter had resented the rise in fortune which the stabs of Guiscard had secured for his colleague, and when he received a viscounty instead of the expected earldom his resentment knew no bounds. Mrs. Masham deserted her cousin for his more vivacious rival. The Jacobites lost faith in his repeated promises. Queen Anne transferred her confidence from Oxford to Bolingbroke; and he surrendered his office a few days before the queen died.

On the accession of George I. the defeated minister retired to Herefordshire, but a few months later he was committed to the Tower (July 16, 1715). After an imprisonment of nearly two years he was released in July 1717, but he took little part in public affairs, and died almost unnoticed in London on May 21, 1724.

The books and the manuscripts which the first earl of Oxford and his son collected were among the glories of their age. The manuscripts became the property of the nation in 1753 and are now in the British Museum; the books were sold to a bookseller called Thomas Osborne in 1742 and described in a printed catalogue of five volumes (1743–45), Dr. Johnson writing an account of the library. A selection of the rarer pamphlets and tracts, which was made by William Oldys, was printed in eight volumes (1744–46), with a preface by Johnson. The best edition is that of Thomas Park, ten volumes (1808–13). In the recollection of the Harleian manuscripts, the Harleian library and the *Harleian Miscellany*, the family name will never die.

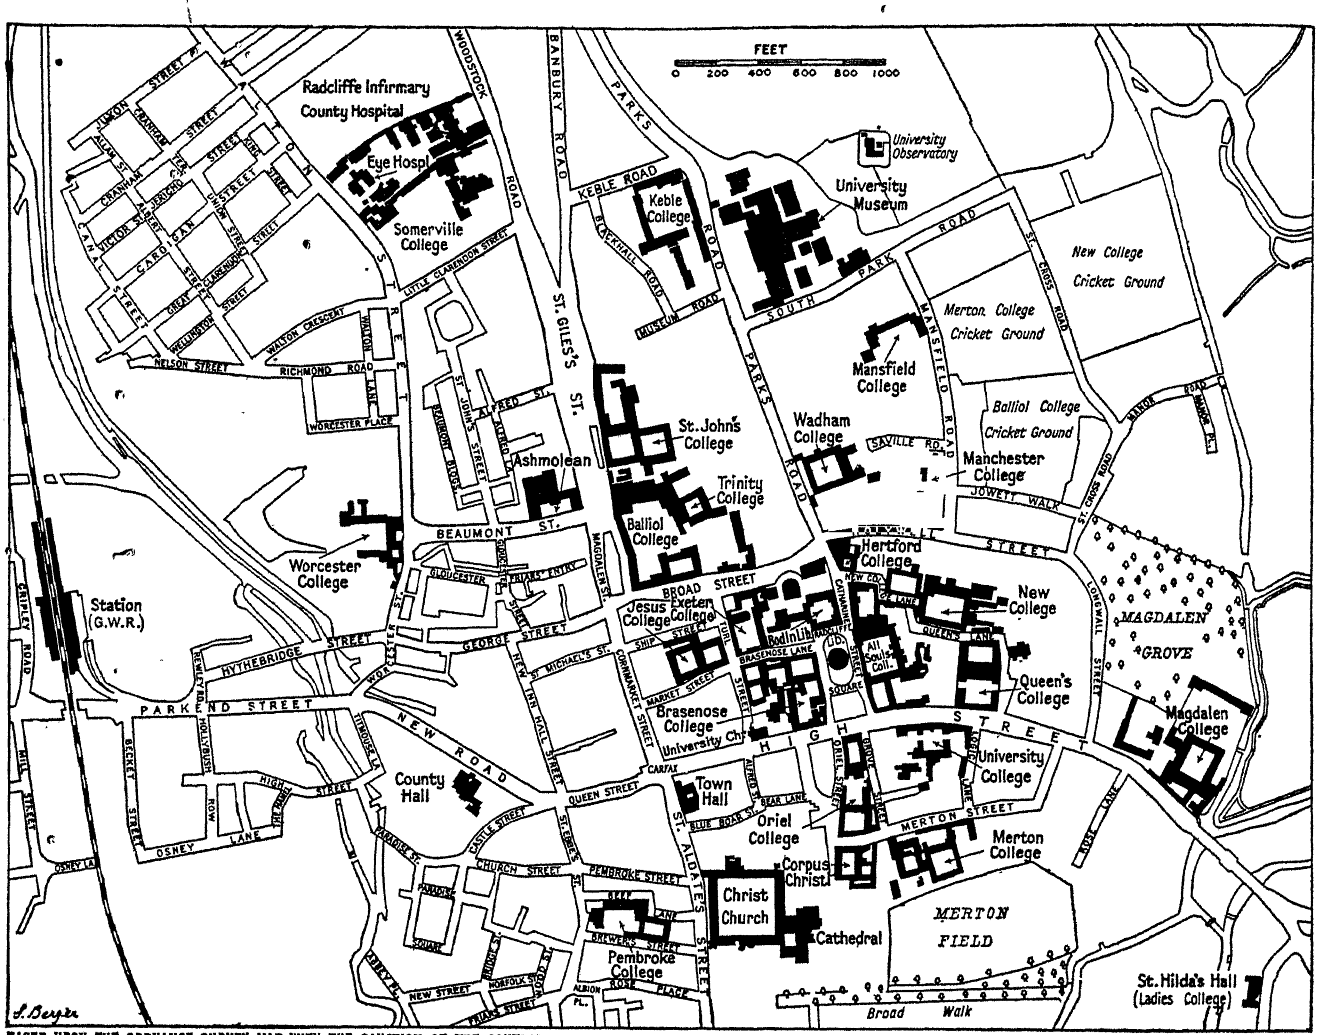
OXFORD, the county town of Oxfordshire, England, a municipal and parliamentary borough, cathedral city, and seat of an ancient university, lies on the river Thames, 51 m. by road and 63¾ m. by rail W.N.W. of London (G.W. railway); main railways also to Worcester and Birmingham (G.W. railway); direct service also via Banbury to Leicester and Sheffield (L.N.E. railway), branch line L.M.S. to Cambridge crossing main line at



BASED UPON THE ORDNANCE SURVEY MAP WITH THE SANCTION OF THE CONTROLLER OF H.M. STATIONERY OFFICE

MAP OF OXFORD, SHOWING THE PRINCIPAL COLLEGES

Bletchley. The Thames is navigable below Oxford; there is a canal to the Avon valley and Birmingham; and numerous local road motor services. Population (1938), 94,090.

The site of Oxford is a low gravel terrace between the upper Thames and its tributary, the Cherwell, which meet in wide water meadows within a gap in a line of oolitic plateaux represented by Headington hill on the East and the twin crests of Cumnor Hurst and Wytham on the west. Though there are sparse Romano-British habitations on both sides of the valley, the Roman road northwards from Dorchester to Alchester lies far back to the east, and only a few finds betray a track across the valley from Headington towards Binsey. Oxford itself only becomes perceptible in Saxon times, in the church of St. Martin (whose dedication and some rude masonry in the tower mark its early date) close to Carfax (Lat. *quadrifurcus*, French *carrefour*) the intersection, in the heart of the city, of north-south and east-west roads. Eastward the High street crosses the Cherwell by Magdalen bridge, and offers alternative routes to London via Headington or Littlemore; southwards St. Aldate's, formerly Fish street, crosses the Thames (Isis) at Folly bridge, for Abingdon and Newbury; northwards, by Cornmarket, are the roads to Banbury and Woodstock; westward, Queen street leads round the south side of the Norman castle to Quaking bridge, over the mediaeval mill stream towards Osney: the modern New road, north of the castle, leads direct to the railway stations and Seven Bridges road for the upper Thames, and south-west England. Early traces are: (1) the Priory (afterwards Augustinian), commemorating St. Frideswide, a local heroine whose good works and adventures, about 720–740, touch also Binsey and Abingdon; of her original church there are arches near her shrine in the cathedral; (2) the conspicuous mound raised (probably about A.D. 900) to command the passage from Mercia into Wessex; (3) Oseney village, beyond the nearest channel of the upper Thames, whose name (Ousen-eye: "water-island") explains the Oksnaforda and Orsnaforda of 10th century Saxon coins, whence *Oxenford* and *Oxford* arose by assimilation to names like Swinford and Shefford. Upstream, between Osney, Binsey and Wolvercote, the "Port Meadow" is still held in common by the freemen of Oxford.

Oxford just appears in history when Edward the Elder, in A.D. 912, "held Lundenbyrg (London) and Oxnaford and all the lands that were obedient thereto" as flanking fortresses of his Thames valley frontier. But the principal centres of the district were not here, but at Abingdon, commanding access to the Vale of White Horse, with an early and wealthy abbey, and Dorchester, similarly dominating the Thames valley, with its pre-Roman earthworks, and Saxon bishopric. River traffic bound for Oxford long paid toll to the abbott of Abingdon. However, several "gemots" were held at Oxford, under Edric, Canute, and Harold I.; and repeated devastation by the Danes (979, 1002, 1010, 1013) attests military and economic importance.

The Norman governor, Robert d'Oiloi (d'Oyly), incorporated the Saxon mound in a great fortress (1170–1219), of which one tower stands, and Bullock lane and St. Peter le Bailey mark the outworks; he built the Hythe bridge, which reveals the terminal wharfs of the river traffic; enclosed the town (partially "wasted" in Domesday) with walls of which foundations remain at the (north) Bocardo gate, the fine tower annexed to St. Michael's church. To d'Oiloi's time belong the rebuilding of St. Frideswide's (the present cathedral dates mainly from the fire of 1120), St. Ebbs' near Carfax, St. Peter's, in the east, probably outside the first

east wall, and Holywell by the Cherwell beyond. His son Robert founded the splendid Osney abbey, beyond the castle (fragments in the cemetery beyond the G.W. railway). Outside the city, also, north of the cattle market in Gloucester Green, Henry I. built his Beaumont palace overlooking Osney and Port Meadow, and under his "Beau-clerc" patronage Theobald of Etampes already, about 1120, was teaching "60 to 100 clerks." As residence of the empress queen Maud, Oxford suffered siege by Stephen.

While domestic business was conducted between the Corn Market and the High, within the walls, the wool fair and strangers' market, outside the north gate, had, about 1200, a church of St. Giles, its patron. Beyond it lay the leper house (later St. Giles' parsonage), and east of it other establishments mainly for strangers, the Scots college of John de Balliol, Durham college (afterwards Trinity), a Cistercian house (afterwards St. Bernard's, then St. John Baptist's college); and, when Beaumont palace was granted by Edward II. to the Carmelites, the Benedictines occupied the site they had left with the older "cottages" of Worcester college. Other Cistercians built Rewley abbey beyond Hythe bridge; Dominican and Franciscan houses in the poorer south-west quarter leave their names in Blackfriar street, Preacher's bridge and Friars wharf; and the Austin Canons of St. Frideswide acquired endowments for teaching and added the Latin chapel to their church. By the mid 13th century then mediaeval Oxford had taken permanent shape. The walls were reconstructed, and probably extended from an older line in Cat street, to include St. Peter's in the east, with an East gate spanning the High near the hotel of that name, between the splendid north-east stretch of wall conserved by New college, and the south-east angle around Merton.

But before this, in the old north-east angle, now occupied by the Bodleian and Radcliffe libraries, "School street" traversed a kind of "Latin quarter" frequented by wandering scholars, whose *universitas* or guild comes into history with the visit of Giraldus Cambrensis in 1185, and the nomination of a chancellor in 1214. (*See* OXFORD UNIVERSITY.) On the south frontage of this resort of scholars, St. Mary's church became their meeting hall and lecture room; its bell tower and spire, congregation house and library were built about 1320; a new nave and aisles replaced, in 1388, the old Faculty chapels; and the Renaissance porch marks Archbishop Laud's reconstitution of the university, and still dates *"in parviso"* the certificates of satisfactory "responsions" of novices to the "masters of the schools" who controlled their admittance. For the history of this university, and the several fortunes of its colleges, *see* below.

The 13th century was the great age of mediaeval Oxford. Several parliaments were held here, notably the "Mad Parliament" of 1256, with its "Provisions of Oxford." But the growth of the university, and the wealth and influence of its colleges, were unfavourable to normal development as a mediaeval borough, with its guilds of craftsmen and traders. The "liberties" of the university, in relation with the city, were defined by charter in 1248, and revised in favour of the "chancellor, masters and scholars" after the town-and-gown riots of St. Scholastica's day, 1354–55, and other occasions; in 1523 the university was even allowed to incorporate all kinds of tradesmen, exempting them from civic jurisdiction. These unusual but once necessary provisions were only revoked or became obsolete with the modern transformation of the university itself, which retains, however, magisterial authority over its students, a censorship of public entertainments, and direct representation on the City Council and Guardians.

The Renaissance and the Reformation affected Oxford mainly through academical controversies, the foundation of a fresh series of colleges, and the creation by Henry VIII. of a bishopric, with St. Frideswide's church as its cathedral, and a chapter, the dean and canons of Christ church, economized out of Wolsey's "Cardinal college." But in the Civil War, Oxford's strategical importance made it the Royalist headquarters. The king retired hither after defeats at Edgehill, Newbury and Naseby; Prince Rupert made hence his raids in 1643. Not till May 1644 was the king forced by the concerted advances of the earl of Essex and Sir W. Waller to evacuate this fortress, and after Cropredy bridge he re-occupied it. Only in May 1646, when all other strongholds were lost and Charles himself had escaped in disguise, was Oxford besieged by Fairfax and surrendered on June 24. The extent of the city at this time beyond the mediaeval wall is outlined by traces of the "Kings Mound," enclosing Holywell, Wadham college (1611) and St. Giles. Though the university was mainly Royalist, the citizens had been secretly Parliamentarian; on both sides were losses, and party feelings were disastrous; and though Cromwell himself was chancellor (1651–57), his successor, Gilbert Sheldon, had much work to restore efficiency; his monument is the Sheldonian theatre, for the business and ceremonies of the reconciled masters; the Clarendon press and the Ashmolean museum, Christ church library and Peckwater quadrangle, large additions to New college and Magdalen, and the total rebuilding of Queen's college, are academical counterpart to a general rebuilding of mediaeval and Tudor Oxford, in the next half century. Though Charles II. held a parliament here in 1681, the restored Stuarts temporarily alienated university loyalty, but in the 18th century the university became Jacobite, and the city strongly Hanoverian. This feud, however, was reconciled at the visit of George III. in 1785, and Oxford passed out of national politics. The city, however, grew but little, until the reform of the university in 1858 admitted "married dons," while restricting membership of congregation to residents within 1½ m. from Carfax. The obstinate opposition of the university to Brunel's project for a "great western" railway system radiating from Oxford; and the restrictive policy of St. John's college, which owned almost all land north of St. Giles', had already aggravated urban congestion. The modern Oxford which emerged includes: (1) northward, a compact residential area, not wholly academic, along the Banbury and Woodstock roads beyond St. Giles', Keble, the Museum and laboratories, and the university parks and college playing fields; (2) eastward, beyond Magdalen bridge, the diverging roads to Marston, Headington, Cowley and Iffley, already enclosed fan shaped suburbs mainly of small dwellings, when the establishment of the Morris motor works at Cowley introduced a new and strenuous element into Oxford's industrial life, hitherto almost confined to the Clarendon press and private printing firms, robe making and tailoring, and the distribution of local dainties, sausages, marmalade, and the like; (3) to west and south, "ribbon development" along the trunk roads has disfigured the water meadows without adding to health or convenience. The real suburban areas here lie beyond, around or upon the Boar's-hill-Cumnor-Wytham upland. The Oxford Preservation Trust, established almost too late in 1927, a town planning scheme, 1925, and a new Incorporation Act, 1928, are attempts to adjust to the strict and peculiar circumstances of the site and its past, the requirements of "post-war" Oxford, with its partially modernized university, its interminable "summer schools" and vacation-conferences, its growing industries, trade, and professional interests, and the perennial stream of tourists. (J. L. My.)

OXFORD, a city of Butler County, Ohio, U.S., 40 mi. N.W. of Cincinnati, at an altitude of 1,000 ft.; on federal highway 27 and the Baltimore and Ohio railroad. Pop. (1950) 6,926; (1940) 2,756.

Oxford is an educational centre, the seat of Miami university (chartered 1809, opened 1824) with which Oxford College for Women (1830) was consolidated in 1928; and the Western college (for women) (1853).

The city was founded about 1800.

OXFORD, PROVISIONS OF, the articles constituting a preliminary scheme of reform enacted by a parliament which met at Oxford on June 11, 1258. King Henry III. had promised on May 2 that the state of his realm should be rectified and reformed by 24 counsellors who were to meet at Oxford for this purpose five weeks later. Twelve of these counsellors were chosen by the king, and 12 by the earls and barons. When the parliament met the 24 drew up a provisional scheme of reform, known as the Provisions of Oxford. By this it was arranged that a council of 15, chosen by four of the 24, should be appointed to advise the king in all matters. The new council was to meet three times a year in parliaments to which 12 commissioners

were to be summoned to discuss the affairs of the realm on behalf of the whole community. Another body of 24 was appointed to treat of an aid. Desiring to limit the power of the king and his household officers, the barons determined to revive the justiciarship, in abeyance since 1234. But they did not want over-powerful great officials. It was therefore decided that one or two justiciars should be appointed for one year who should be paid, but should be accountable at the end of the year. The chancellor and treasurer similarly had to account; the sheriffs, too, were appointed for one year only. Enquiries into abuses were begun and further reforms were to be reported on by Christmas. The king declared his adhesion to the Provisions on Oct. 18.

Disputes broke out in the baronial party. Simon de Montfort, earl of Leicester, supported by Edward, the king's son, demanded the logical extension of the reforms in local government to include the baronial franchises. The earl of Gloucester opposed this. Forced by Edward, a second series of Provisions, known as the Provisions of Westminster, was issued in Oct. 1259. The quarrels among the barons encouraged Henry to break free. On April 13, 1261, a papal bull absolved him from his oath to observe the Provisions. After three years on the verge of civil war, both parties agreed to refer the question to the arbitration of Louis IX. of France, who formally annulled them on Jan. 23, 1264, but expressly declared that his decision was not to invalidate the privileges, liberties and laudable customs of the realm of England, which had existed before the time of the provisions.

Tout, *Chapters in the Administrative History of Mediaeval England* (1920); and E. F. Jacob, *Studies in the Period of Baronial Reform and Rebellion* (1925).

OXFORD AND ASQUITH, HERBERT HENRY ASQUITH, 1st Earl of (1852–1928), born at Morley, Yorks., on Sept. 12, 1852. His origins were Liberal, Nonconformist and middle class in character. Joseph Dixon Asquith, his father, owned a cloth manufacturing business in Morley, and his mother was the daughter of William Willans, a Huddersfield merchant. His father died while he, his brother (who afterwards became a master at Clifton), and his sister were children, and the two boys were left in the care of an uncle in London, where they went to the City of London school, then under the able headmastership of Dr. Abbott. Upon him the future prime minister made a deep impression, and to him Asquith in after life was accustomed to express a great debt of gratitude. He won a Balliol scholarship, and at Oxford he took a Craven university scholarship and firsts in "Mods" and "Greats," became president of the Union and a fellow of his college.

Adopting the bar as a profession, he first attracted public notice by his defence of Cunninghame Graham and John Burns for their part in the riot in Trafalgar square, but it was the Parnell Commission, in 1889, in which he acted as junior to Sir Charles Russell, that established his legal reputation, his deadly cross-examination of the manager of *The Times* giving the first indication of the dramatic issue of the trial. His success at the bar was assured, and in the next year he took silk, but the law was only a stepping-stone to the political career that from boyhood he had always had in view. He had entered parliament as member for East Fife in 1886, and on the formation of the Gladstone Government in 1892 he was appointed home secretary. He had just previously sustained a heavy domestic blow by the death of his wife, Helen, the daughter of a Manchester surgeon, whom he had married in 1877 and by whom he had four sons and one daughter. In office, Asquith's great parliamentary gifts were at once apparent, and his administration of the Home Office was made memorable by the appointment of the first women inspectors, improvements in the administration of the Factory Acts, the stiffening of the machinery, and the passing of the Employers' Liability bill, which was rejected by the Lords, and of a Factory bill which became law. He was bitterly and most unjustly attacked in connection with the shooting of two miners by soldiers who were called in to deal with a strike at the Featherstone colliery. He did not summon the soldiers, and appointed a commission immediately to enquire into the affair, but the legend that he was personally responsible pursued him, and for years his platform appearances were always greeted with cries of "Featherstone."

In 1894, while still at the Home Office, Asquith married a second time, his bride being the brilliant Miss Margaret ("Margot") Tennant, one of the daughters of the wealthy iron-master, Sir Charles Tennant. She was a prominent member of the most exclusive society circle, and the marriage very definitely changed the current of Asquith's social life, and in some measure affected his political relationships. The period was one of great disruption within the Liberal Party. The feud between the Rosebery and Harcourt groups was at its height, and after the fall of the Liberal Government in 1895, the conflict with the Boer republics divided the party into two hostile camps, the Liberal Imperialists, led by Lord Rosebery, and the pro-Boers led by Campbell-Bannerman. Asquith, who had returned to the bar, associated himself with the Rosebery group, which endorsed the Chamberlain policy. In this he was influenced, no doubt, by his confidence in Sir Alfred Milner, who had been his friend from his Balliol days, and who had become the instrument of British policy in South Africa. When the Boer controversy culminated in war, it seemed that the quarrel between the Roseberyite and Campbell-Bannerman factions must result in permanent separation, and the formation of the Liberal League, of which Lord Rosebery was president and Asquith vice-president, apparently put reconciliation out of the question.

From this catastrophe the Liberal Party was saved by the raising of the Tariff Reform issue. On this subject Lord Rosebery spoke with an equivocal voice, but Asquith at once became the most formidable protagonist of Free Trade. The discussion of the subject became largely a duel between him and Chamberlain, and the series of speeches he delivered throughout the country were among the most conspicuous triumphs of his career. It restored him to the full confidence of the party, and when Campbell-Bannerman formed his Government at the end of 1905 his appointment as chancellor of the exchequer was a matter of course. The moderation of his temper, and the entirely public-spirited motives that always inspired him. contributed to the return of harmony within the party, and his achievements as chancellor established his claim to the succession to the premiership. His record at the Treasury, culminating in his final budget, which inaugurated old age pensions, give him a place among the most illustrious chancellors in history. On the resignation of Campbell-Bannerman, through illness, in 1908, Asquith became prime minister by universal consent, with Lloyd George as chancellor of the exchequer. No prime minister since Pitt had been called upon to face such grave issues as those which confronted Asquith at the beginning and developed as his long term of office—the longest of any prime minister since Lord Liverpool—advanced. A new mood of revolt filled the labour world with unrest and menace, the long struggle for the enfranchisement of women had passed out of the academic phase into a phase of unprecedented and almost fantastic violence, the sky over Europe was visibly darkening with the naval activity of Germany, and over and above all two capital issues reached a crisis—the issue of the House of Lords and the issue of Ireland. It was the first of these two questions that first tested the stuff of which the new prime minister was made. The budget of 1909, which dealt with the taxation of land, was rejected by the House of Lords. Asquith appealed to the country against its rejection in Jan. 1910, and his Government was reinstated, though only with the support of Labour and the Irish members. He addressed himself forthwith to the question of the abolition of the veto of the House of Lords, and during the summer made efforts to reach a pacific solution of the question by compromise. But the conference with the Opposition leaders broke down, and in the following December he appealed once more to the country and was once more returned, —this time with a majority over the opposition of 126.

The opening of the session of 1911 may be taken as the crowning moment in Asquith's public career. The issue of the constitutional struggle with the Lords was not yet decided, but it was

no longer in doubt. The decisive mandate which the country had given in December dictated the issue that immediately occupied the new parliament. A bill abolishing the veto of the House of Lords was introduced into the House of Commons and passed all its stages by the beginning of the summer. But the final struggle had yet to come. The battle had still to be won in the Lords and there the opposition were entrenched in overwhelming power. Ever since the emergence of the issue it had been evident that the attainment of Asquith's goal depended on whether he could in the last resort invoke the authority of the Crown to dilute the House of Lords with new peers sufficient to change its complexion. The question was answered on July 20. The Parliament Bill, then in the House of Lords undergoing its second reading, was so amended as to deprive it of any utility for the purpose for which it was framed. Asquith therefore addressed to Balfour, the leader of the Opposition, a letter stating that the Government had decided, if the bill in its essential form could be passed in no other way, the Crown would be advised to create a sufficient number of peers to ensure its passage, and that the Crown had signified its willingness to accept such advice. The publication of this letter aroused an unprecedented storm, and on July 24, on rising in the House of Commons to make a statement, Asquith was greeted with a demonstration without parallel in living memory. For the best part of an hour he stood speechless before the roar of anger that issued from the Opposition benches, and at last resumed his seat without having uttered a continuous sentence. What became known as "the pothouse brawl" inaugurated the last stage of the struggle. The Government was accused of "dragging in the King," and the Opposition organized an uncompromising resistance in the belief that they would not dare to carry their threat into execution. But on Aug. 10, when the final debate was taking place in the House of Lords, Lord Morley confirmed the Government's previous intimation of His Majesty's intention. Up to this point the "Die-Hards" seemed to be assured of a majority, but in the division they were defeated. The bill was passed. On Aug. 18 the Parliament Act received the Royal Assent.

From this victory Asquith proceeded to his next great task, with the ground sensibly cleared for action. Gladstone's successive Home Rule adventures had broken on the rock of the Lords' veto; that rock no longer obstructed the channel. But before the Irish issue was fully launched another controversy absorbed the prime minister's activities. Discontent had long been growing prevalent in the mining industry, and at the end of Feb. 1912, having failed to secure the concessions and advances they demanded, the miners' union declared a strike. Vast dislocation followed. From the outset the Government endeavoured to bring the conflicting parties to agreement and Asquith took on himself the personal charge of the negotiations. After a month's fruitless efforts, the Government thereupon introduced the Miners' Minimum Wage Bill, which, by providing a half-way solution, forced the hands of both sides and brought the immediate struggle to an end, although the issue incidentally raised—that of the reorganization and control of the coal industry—was to perplex parliament and the country for many years to come.

Meanwhile, the Home Rule Bill had been introduced and passed through the House of Commons, while the Parliament Act provided adequately against the resistance of the House of Lords. That House fought the delaying action, which was all the Opposition now had in its power, by rejecting the bill in two successive sessions. After its next passage through the Commons it would have overridden opposition and automatically become law. By this time, however, the opposition to the measure had taken an extra-parliamentary shape. The Ulster Covenant had been promulgated in the previous September and talk of open rebellion, should Home Rule be passed, was already current. In June arms had been discovered both at Belfast and Dublin. As the year wore on the outlook became still more serious and a speech by Bonar Law, the leader of the Conservative Party, at Blenheim, seemed to give encouragement to the idea of resistance by force. On Sept. 25 the Ulster Unionist Council appointed a Provisional Government and prominent Conservatives openly preached armed resistance; Sir Edward Carson, the leader of the Ulster Unionists, left no doubt that in the last resort Ulster would fight.

With the close of the session of 1913 there came a brief lull, and during the recess conversations with the Opposition leaders were opened by Asquith, who throughout preserved an attitude of patience and forbearance. It will always be matter for controversy whether, when the policy of violent resistance had been adopted, he was justified in ignoring so direct a challenge to constitutional government. His natural disposition was to allow the utmost scope for the play of discussion and the influence of the time element; but it is an open secret that he would have taken up the challenge but for the persuasions of John Redmond, the leader of the Irish Nationalists, who believed that the prosecution of the Ulster leaders would prejudice the prospects of friendly relations with Ulster when Home Rule was actually on the statute book. In any case, the conversations of the autumn were futile, and on March 9, 1914, the Government announced the provisions of their amending bill, their last word of compromise. The chief provision of this bill was that any county in the north of Ireland was to be allowed to vote itself out of the operation of Home Rule for a period of five years.

The offer was rejected by the Opposition and now events rushed forward to an apparently unavoidable catastrophe. On the night of April 24–25, 55,000 rifles were landed at Larne from a German port for the use of the Ulster army. On the other side of the border the Nationalists were beginning to enrol a volunteer army and to make counter-preparations. Meanwhile a more sinister menace appeared. In the debate on the vote of censure on the Government on March 19 Bonar Law, speaking on the Home Rule issue, had used the ominous phrase "soldiers are citizens like the rest of us." There had been much talk of disaffection in the army in regard to the coercion of Ulster, and on March 20 it took shape in the Curragh incident (*see* IRELAND; IRELAND, NORTHERN), which led to the resignation of Col. Seely, the secretary for war. For a moment it seemed that the loyalty of the army was imperilled and the situation that confronted the Government looked desperate. But the announcement by Asquith next day that he would assume the secretaryship for war created a profound impression in parliament and stopped for the time being, at all events, what had seemed like a riot in the army. Following the mutilation of the amending bill by the House of Lords and Sir Edward Carson's challenge to the Government to "give us a clean cut or come and fight us," the king, on Asquith's advice, summoned a conference at Buckingham Palace on July 20 to see if some agreement was still not possible. It broke down four days later and the last hope of avoiding violence seemed gone.

What Asquith would have done to avert a civil war while maintaining the authority of the Constitution was not to be revealed, for on the day that the Buckingham Palace Conference broke up Austria sent her ultimatum, and within ten days the British army was embarking, not for Ulster, but for Flanders. In the feverish struggle within the Cabinet that preceded the entry of Great Britain into the World War Asquith's position was never in doubt. He had throughout been a party to the ambiguous military understandings and conversations which had been in progress with France since before the fall of the Balfour Government in 1905, and when the war came he did not waver in his conviction that both the duty and the interest of the country lay in throwing the country's whole weight into the scales against what he considered to be the calculated design of the Central Powers to establish a military despotism over Europe.

The invasion of Belgium by Germany saved his Government from disruption, and he addressed himself, free from domestic disquietudes, to the heaviest task ever imposed on a British prime minister. For the moment even the Irish trouble subsided, all political differences were shelved and Asquith became the voice of a united nation in a measure unequalled in modern Parliamentary history. The speeches he delivered in the early days of the war have taken their place beside the classic orations of Pitt during the Napoleonic wars, and his constancy of mind and freedom from all personal ambition played a dominating part during the next two years in laying the foundations of the ultimate victory. It was not to be expected that in the presence of so vast a con-

vulsion discontents would not develop. They became clamant as the true character of the struggle emerged. Asquith had made no change in the political constitution of his cabinet at the outbreak of war, although he had taken the leaders of the Opposition into his confidence and private counsels, but by the spring of 1915 it became clear that this informal relation would have to yield to a formal coalition.

In February Bonar Law and Lord Lansdowne intimated that they could accept no responsibility for the way in which the war was being conducted, and in the popular press a powerful and ceaseless agitation arose, directed mainly against Asquith, Grey and Haldane, and inspired by the inevitable shortage of munitions which the progress of the war had revealed. Coincidentally, a violent disagreement as to the employment of the navy in the Gallipoli adventure had arisen between Churchill, the first lord of the Admiralty, and Fisher, the first sea lord, and on May 26 Asquith reformed his cabinet on a coalition basis, bringing in the leaders of the Opposition and excluding Haldane. To meet the growing need for munitions, a special Ministry of Munitions was set up with Lloyd George at its head.

The reconstruction of the Ministry did not allay dissatisfaction. Within the cabinet friction developed, and, outside, the press agitation grew in violence. There was a persistent leakage of cabinet secrets, certain newspapers betraying a knowledge of most confidential Government business with such regularity as to suggest inspiration. A phrase, "Wait and See," which Asquith had used in reply to a question in the House of Commons years before, became the daily gibe of the malcontent press, and Sir Edward Grey, then in the midst of the most delicate situation with the United States, was accused of "feeding Germany" because of his attitude on the subject of contraband from America. The war-weariness that had overtaken the country provided an atmosphere in which this propaganda of discontent flourished, and the prime minister was the easier target for attack because he neither "squared" the press nor hit back at his critics. The inevitable rupture came in the autumn of 1916, when the German raid into Rumania—now seen in its true proportions—served to drive home the attack, and when Asquith was severely stricken by the loss of his eldest son in the war.

It arose over a question of cabinet reorganization. For some time the formation of an inner cabinet had been under discussion. At the beginning of Dec. 1916 Lloyd George, who upon the death of Kitchener had become secretary for war and whose prestige with the press had long been in the ascendant, submitted a definite scheme for the formation of such a body. From this body the prime minister was to be excluded. His right to control policy was not challenged, but he would not direct the deliberations of the inner cabinet. The *coup* burst upon the country with the announcement of the popular newspapers that Lloyd George was "packing up" in sheer despair at the inefficient conduct of the war. His highly confidential challenge to the position of Asquith was under consideration when an article appeared in *The Times* (then owned by Northcliffe) giving full details of the supposed arrangements and suggesting that Asquith had already agreed. Lloyd George denied any knowledge of this article; but Asquith, after consulting with his friends, decided to reject the proposal. Upon this Lloyd George resigned, being followed by other influential members of the cabinet—including some who hoped that their action would give the prime minister the opportunity of reforming his cabinet on a new basis—Asquith informed the King that he could no longer be responsible for carrying on the business of government; and within a few days the second Coalition Government was formed with Lloyd George as prime minister. (*See* ENGLISH HISTORY: *The Twentieth Century;* WORLD WAR I.)

Thus ended Asquith's long and memorable tenure of the premiership. For the remainder of the war he occupied a seat in the front Opposition bench, speaking rarely and only on occasions when the interest of the nation seemed to demand his intervention. At the election of 1918, when Lloyd George swept the country with an appeal for the maintenance of the Coalition, he did not escape the general wreck of the Liberal Party, losing the seat of East Fife, which he had held throughout his parliamentary career. In 1920 he returned to the House of Commons as member for Paisley and resumed his position as head of the remnant of the succeeding parliaments. In 1924, after an election fought on the issue of protection, he, as the head of a pivotal majority, was responsible for the accession to power of the first Labour Government, and later in the year for the Government's overthrow on a question of alleged governmental interference with the prosecution of a communist. At the next election he was defeated and retired to the Lords as earl of Oxford and Asquith.

Other honours were conferred on him. He became a member of the judicial committee of the privy council, a knight of the garter and a fellow of the Royal Society. After he entered the House of Lords he rarely intervened in public discussion. But at the outbreak of the General Strike in 1926, he urged the paramount duty of concentrating on the struggle against the "coercion of a new dictatorship," though he blamed the Government for not taking steps during the preceding nine months to make constructive proposals for the coal industry. Some recrimination followed, and there was a split in the Liberal Party (*q.v.*). He still retained the leadership of the Liberal Party, to which Lloyd George had now returned. But on the outbreak of the General Strike in 1926 a sharp difference appeared in the attitude of Lord Oxford and Lloyd George towards the event, and the latter declined to consult his colleagues. Lord Oxford thereupon formally intimated that he could have no political relations with him, and as the result of the consequent breach Oxford retired from any active part in the affairs of the party which he had led for 18 years. In his retirement he devoted himself to writing a book of reminiscences and reflections, under the title of *Fifty Years of Parliament,* and in the autumn of 1927 he also published a volume of his speeches. Thereafter his health gave way and he died on Feb. 15, 1928, being buried, according to his wish, in the churchyard of All Saints church, Sutton Courtney, Oxfordshire, where he had long had a country home.

Asquith will take his place among the most illustrious of British prime ministers, not merely by virtue of the momentous events in which he played a part, but still more because of his remarkable parliamentary gifts. In this respect he was in the true succession to Gladstone. He had little of the Sinaitic fervour of that great man, but he was not inferior to him in his mastery of the House of Commons. That mastery was achieved, not by emotional passion, but by the force, direction and lucidity of his speech, the intellectual sovereignty that he exercised over his audience, and the qualities of a plain, unaffected character and a singularly dispassionate mind. No man who ever played a great part in affairs was more conspicuously free from the common vices of public life. If he was ambitious it was only the ambition of conscious power directed to public ends. He was the least egotistic of men, and his magnanimity almost bordered on weakness. He was so little of a demagogue that he seemed to avoid rather than invite popular applause, a character to which a certain temperamental shyness contributed. His loyalty to his colleagues, even when they were lacking in loyalty to him, was one of his most striking attributes, and he was so indifferent to his own interests that he not only allowed the praise that belonged to himself to be appropriated by others, but often assumed the burden of mistakes which others had committed. He was the antithesis of that 18th century statesman of whom it was said that if there was credit to be got no one was so skilful in wriggling in, and if there was discredit to be borne no one was so skilful in wriggling out. He bore the odious slanders and insults of a demented press during the war with a certain proud and indifferent scorn, and his bearing both in private and public after the consummation of the intrigues against him was a model of dignity and public spirit. He was never betrayed into violent speech. and if his passion were roused, it was roused, not by personal issues, but by the outrages against public law and the sanctity of constitutionalism. He shared with the younger Pitt the view that the greatest quality in statesmanship was patience, and in all the perplexities with which he had to deal he exercised that quality to the utmost. He would never force a situation while there was a hope that a reasonable and pacific solution could be found. This confidence in the beneficent

operation of rational processes led many to suspect him of weakness, and it is undoubtedly true that there was in him an indisposition to anticipate events or to indulge in the histrionics of statesmanship. But on vital issues he was adamant, and his judgment on all great matters was never vitiated by the smaller considerations of personal and irrelevant motives. His mind moved in the undistracted orbit of a deeply considered philosophy of government, and it may be said of him, as of another, that if he was sometimes on the wrong side, he was never on the side of wrong. He will live in history not only as one of the most illustrious of British premiers but as a type of all that is best in the English character.

The general affection and regard in which Oxford was held was shown by the gift, in 1927, from 17 of his friends and admirers, including some Conservatives, of a capital sum and an income for life. By his first marriage he had four sons and one daughter. Raymond Asquith, his brilliant eldest son, was killed in action in 1916. By his second marriage he left a son, Anthony, and a daughter, Elizabeth, Princess Bibesco. He was succeeded in the earldom by his grandson, Julian, only son of Raymond Asquith.

OXFORD AND ASQUITH, Margot, Countess of (1864–1945), the sixth daughter of Sir Charles Tennant, 1st Bart., married, in 1894, as his second wife, H. H. Asquith, later the Earl of Oxford and Asquith (*q.v.*). Before her marriage she was well known as a member of the coterie known as the "Souls," and maintained her reputation as one of the wittiest and most brilliant women in London society. In 1922 she published *The Autobiography of Margot Asquith* (2 vol.), which reflected the natural frankness of her character. It is a valuable chronicle of the time. She died in London on July 28, 1945.

Her other works include *Places and Persons* (1925), *Lay Sermons* (1927) and a novel *Octavia* (1928).

OXFORDSHIRE or Oxon, a southern midland county of England, bounded northeast by Northamptonshire, northwest by Warwickshire, west by Gloucestershire, south-southwest and southeast by Berkshire and east by Buckinghamshire. It was originally part of the Mercian kingdom; but its boundaries, except for the Thames on the south (71 mi. from Kelmscot near Lechlade, Gloucestershire, to Remenham below Henley-on-Thames, with the exception of two points near Oxford), are artificial. They were slightly changed by act of William IV and Victoria and by the Reading extension order of 1911 and enclose an area of 748.8 sq.mi.

The 14 Oxfordshire hundreds include five of the Chiltern hundreds, the jurisdiction over which belonged to the manor of Benson and in 1199 to Robert de Harecourt.

Structure and Topography.—The county lies across the central portion of the Jurassic and Cretaceous outcrops. The strike of the strata is in each case from north-east to south-west, for Tertiary movements have tilted them gently down to the south-east so that the transition from north-west to south-east is from older to newer rocks passing in succession from the Lias over the Lower, Middle and Upper Oolite to the Lower Greensand, Gault, Upper Greensand and Chalk. In the north-west, the Marlstone of the Middle Lias and the Limestones of the Oolitic series are permeable and relatively resistant, and the Marlstones and the Inferior Oolite rocks being specially hard, stand out as a sharp north-west edge, continuing the line of the Cotswolds at a lower level (average 500 ft.), but rising to 700 ft. in Edge Hill in the north-east of the county. In the south-east, the chalk is also permeable and resistant, and the hard chalk-with-flints crowning the Chilterns also presents a sharp edge to the north-west.

Between these two upland regions the intermediate geological series forms a broad vale (20 m.) of alternating clays and calcareous, sandy beds. The Upper Greensand forms a low feature at the foot of the chalk hills; this is succeeded by the Gault, with width of outcrop varying from 4 m. to 1½ m. between Dorchester and Sydenham. The lower Greensand appears from beneath the Gault at Culham and Nuneham Courtney and in outliers north of Cuddesdon; Portland limestone, Portland sands and Purbeck beds lie between it and the Kimmeridge clays, which outcrop between Sandford and Waterperry. Coral Rag is traceable from Sandford to Wheatley and beyond this comes a broad outcrop of Oxford clay followed by the Cornbrash (a brownish rubbly limestone). This outcrops at Norton Bridge, Woodstock and Shipton, forms a broad plateau between Middleton Stoney and Bicester, and also occurs as inliers at Islip, Charlton, Merton and Black Horse Hill. The county lies almost wholly in the basin of the upper Thames, in which the significant drainage is that of the Cherwell-Thames. The drainage pattern as a whole, consists of numerous consequent streams from the scarplands (Evenlode, Windrush, etc.), which have been captured and diverted into the Cherwell-Thames by powerful subsequent streams (Ock, Upper Thames, Ray, Thame), working along lines of weakness in the strike of the rocks, obsequent streams flowing down the scarp edge often being a further result of the capturing.

The Cherwell occupies a broad sag between Edge Hill and the Northampton Uplands. It flows south-south-east, joins the Thames coming from the west at Oxford, after which the combined stream continues the south-south-east direction, passing by a deep gorge through the chalk between Wallingford and Reading. That the gap must have originated north-west of its present position is argued from the fact that the level of the river bed at this point is 100 ft. while that of the hills on either side is 700–800 feet. It is an old, but rejuvenated drainage system, which, working upon calcareous rocks, has given rise to a characteristic topography; streams graded to base level but with very steep-sided upper valleys and wide intervening spaces between the head streams that have no surface streams; broad main valleys from which streams have disappeared, or where drainage is beneath the surface; misfit streams, due to capture by the river Severn of an earlier drainage to the Thames from the Welsh plateau, or to carving out of valleys by flood waters following the retreat of the ice. There is little glacial drift except in the north-east of the county. Gravel deposits, both plateau (North Leigh, Combe, Tiddington, etc.) and flood plain (Bampton, Oxford, Dorchester, etc.), are very important; tracts of clay-with-flints, brick-earth and gravel, as well as outliers of the London clay (Nettlebed, Caversham, etc.) occur on the dip slope of the chalk.

History and Early Settlement.—The bare Lias and Oolite uplands and the flood plain gravels were sites of late Neolithic settlement, as witness numerous Long Barrows (characteristic of the Cotswold area) as far east as the Cherwell. The Rollright stones (probably Neolithic) on the Oolite scarp need special mention. Quantities of bones of cattle, pigs, sheep, etc., are found in the gravels, and pottery (characteristic of the Wash area) is distributed east of the Cherwell-Thames line. Settlement on the dip slope of the Chilterns was debarred by forests, as also in the forested north-eastern portion of the county, but the Icknield Way, generally on the Greensand, and the Ridgeway, on the Chalk above, followed the scarp face to the Thames crossing, forming parallel routes to a trackway along the limestone uplands. An influx of the people who made Beaker pottery is indicated for the region between the Evenlode and the Windrush and on the valley gravels (Eynsham, Stanlake, Brighthampton, Oxford, Burcot, Dorchester, etc.). In the Iron Age camps were established along the same routes (*e.g.*, Chastleton, Tadmarton). During the Roman period the area was thickly populated and roads were made linking Alchester and Dorchester in the Cherwell-Thames with Towcester (Northamptonshire) to the north and Silchester (Hampshire) to the south. Alchester was also connected by Akeman Street with Verulamium (Hertfordshire) to the east and Cirencester (Gloucestershire) to the west. The Saxon settlements are noticeably on valley sites, occupied in pre-Roman times, and these have continued as nucleated settlements to the present day; isolated farms are noticeably on plateau or vale from which forest was cleared comparatively late. In the 6th century the West Saxons took Benson and Eynsham. (*See* the *Saxon Chronicle* for 571.)

In the 7th century the Mercians held all the northern border of

the Thames, and during the 8th century this district fell to Wessex after the battle of Burford, and to Mercia after a battle at Benson, when it was included in the diocese of Lincoln. The bishopric at Dorchester given to Birinus (the apostle of Wessex), 634, seems to have come to an end on the establishment of the see of Winchester. Before the Mercian conquest in 777 Oxfordshire was in the diocese of Sherborne. In 873 the jurisdiction of Dorchester reached to the Humber, and when the Danes were converted it extended over Leicestershire and Lincolnshire, Oxfordshire forming about an eighth of the diocese. In 1092 the seat was transferred to Lincoln. In 1542 a bishopric of Osney and Thame was established, taking its title from Oxford, the last abbot of Osney being appointed to it. In 1546 the existing bishopric of Oxford was established. The ecclesiastical boundaries remain as they were when archdeacons were first appointed—the county and archdeaconry being conterminous. The county, excepting the parish of Taynton in Chelmsford diocese, is in the diocese of Oxford.

The Danes overran the county during the 11th century; Thurkell's army burnt Oxford in 1010, and the combined armies of Sweyn and Olaf crossed Watling Street and ravaged the district, Oxford and Winchester submitting to them. At Oxford, in 1018, Danes and Englishmen chose Eadgar's law. Here also Harold allowed Tostig to be outlawed and Morkere to be chosen earl in his place, thus preparing the way for his own downfall and for the Norman Conquest. The destruction of houses in Oxford recorded in the Domesday Survey may possibly be accounted for by the ravages of the rebel army of Eadwine and Morkere on this occasion. Large possessions in the county fell to the Conqueror, and to Odo, bishop of Winchester. The bishop of Lincoln and many religious houses (*e.g.*, Abingdon, Osney and Godstow) held much land in the county. Robert D'Oiloi, heir of Wigod of Wallingford, held many manors and houses in Oxford, of which town he was governor. The importance of Oxford was already well established; the shire moot there is mentioned in Canute's Oxford laws, and it was the seat of the county court from the first, the castle being the county gaol. For events between this period and the Civil War *see* OXFORD (city). The dissolution of the monasteries, though it affected the county greatly, caused no general disturbance.

When King Charles I. won the battle of Edgehill (Oct. 23, 1642), Oxford at once became the stronghold of the royalist cause. For the campaign of 1643 its rôle was to detain the main parliamentary army until the royalists from the north and the west could come up, after which the united forces were to close upon London. More than once, notably at Chalgrove Field (June 18, 1643), Prince Rupert's cavalry struck hard and successfully. In the campaign of Newbury skirmishes took place as the parliamentary troops under Essex passed through north Oxfordshire on their way to the relief of Gloucester, and at the close of the campaign the fortresses of the county offered the defeated royalists a refuge which Essex was powerless to disturb. In the following campaign Charles abandoned the idea of an envelopment and decided to use Oxfordshire as the stronghold from which to strike in all directions. Material wants made it impossible for Charles to maintain permanently his central position, and eventually Essex headed for the south-west, leaving Waller to face the king alone. The battle of Cropredy Bridge followed (Jan. 29), and the victorious king turned south to pursue and capture Essex at Lostwithiel in Cornwall. In the operations of 1644 Oxfordshire again served as a refuge and base (Newbury and Donnington).

On the appearance of Cromwell and the New Model army a fresh interest arose. Leaving Windsor (April 20, 1645), the future Protector carried out a daring cavalry raid. He caught the royalists unawares at Islip, pursued the fugitives to Bletchington and forced the governor to surrender. He swept round Oxford, fought again at Bampton, and rejoined Fairfax, in Berkshire. A few days later Charles again marched northwards, while Fairfax was ordered to besiege Oxford. Charles was compelled to turn back to relieve the city, and the consequent delay led to the campaign and disaster of Naseby. Yet even after Naseby Oxfordshire still retained its importance, but in 1646 the Roundheads closed in from all sides and Stow-on-the-Wold witnessed the final battle of the war. On May 9 Banbury surrendered, on June 24 Oxford capitulated, and three days later Wallingford, the last place to give in, followed its example.

Architecture.—The limestone of the Oolite series has provided beautiful material for both ecclesiastical and domestic architecture, the castles, of which there are few, were probably built for temporary defence in the civil strife of Stephen's reign (1100–1135). Considerable portions of the Norman Oxford castle survive, and slighter remains of the castle at Bampton, the seat of Aylmer de Valence in 1313. Among remains of former mansions Greys Court near Henley-on-Thames (14th century), Minster Lovell, on the Windrush above Witney, and Rycote, between Thame and Oxford may be noted. Minster Lovell was the seat of Francis, Lord Lovel, the son of a Lancastrian who incurred the hatred of that party by serving Richard III.; he afterwards aided Lambert Simnel, and mysteriously disappeared after the battle of Stoke.

Rycote is of fine Elizabethan brick and in the chapel attached to the manor there is remarkable Jacobean woodwork, the entire fittings being of this period. Here Elizabeth resided both before and after her accession. Broughton castle near Banbury (14th century), Shirburn Castle (mainly 15th century Perpendicular) and Stanton Harcourt (1450, with a gatehouse of 1540, a vast kitchen and Pope's Tower) are ancient mansions still inhabited. Mapledurham, on the Thames above Reading, is a fine Tudor mansion of brick; and Water Eaton on the Cherwell, is a singularly perfect Jacobean house of stone.

A large number of monastic foundations arose in the neighbourhood of the university; Augustinian at Bicester, Caversham, Cold Norton, Dorchester, Osney (a magnificent foundation just outside the walls of Oxford) and Wroxton; Cistercian at Bruern and Thame; Benedictine at Cogges, Eynsham, Milton; Mathurin at Nuffield; Gilbertine at Clattercote; Templar at Sandford-on-Thames.

Gosford possessed one of the only two preceptories of female Templars in England. Of all these, excepting the abbey church at Dorchester, remains are scanty. The boundary walls still stand of Godstow nunnery on the Thames, the retreat and burial place of Rosamund Clifford, or "Fair Rosamond," the object of Henry II's famous courtship.

In ecclesiastical architecture Oxfordshire, apart from Oxford itself, is remarkably rich, but nearly all the churches are of mixed dates. Iffley, Adderbury and Minster Lovell are types of a single style. Iffley, 1 mi. S. of Oxford, is one of the finest examples of pure Romanesque in England, with a highly ornate west front. Adderbury, 4 mi. S. of Banbury, is a great cruciform Decorated church with a massive central tower and spire. Minster Lovell, also cruciform, is pure Perpendicular; its central tower is supported on four detached piers.

The short, ungainly spire of Oxford cathedral was among the earliest, if not the first, constructed in England and served as a model from which were probably developed the splendid central spires of the great churches at Witney, Bampton, Shipton-under-Wychwood and Bradwell. There are also fine spires at Bloxham, Adderbury and King's Sutton (in Northants).

Bloxham church, mainly Decorated, with Romanesque portions and a remarkable Early English west front is one of the largest and most beautiful in the county. In the west, Burford (Romanesque and later) is noteworthy, and in the porch of the fine Romanesque church of Langford is a crucifix with the figure cloaked. At South Leigh, Beckley and Swinbrook are remarkable mediaeval mural paintings, while at Caversfield there is what is probably the oldest church bell in England—cast before 1219. About 5 mi. north of Oxford there are Kidlington (Decorated), with a beautiful needle-like Perpendicular spire, and Islip, as the birthplace of Edward the Confessor. Ewelme church (Perpendicular) is remarkable for the tomb of Alice, Duchess of Suffolk (1475), gorgeous with tracery and gilded canopy, and that of Sir Thomas Chaucer (1434), with enamelled coats of arms.

Here William de la Pole, Duke of Suffolk, founded in 1436 the picturesque hospital and free school still standing.

Climate and Agriculture.—The climate, healthy and dry,

except in the low ground bordering the Thames, is colder than the other southern districts in England, especially in the exposed regions of the Chilterns. The county is essentially rural. The surface soils lie in belts, corresponding to the underlying rocks, the heavy clays giving rise to grasslands and the calcareous, sandy soils to arable. Many villages occur where springs issue at the junction of permeable and impermeable strata, thus securing flood-plain pasture for cattle, upland pasture for sheep and upland patches of lighter soil, with a sandy aspect, which could be worked by primitive communities often with a two-field rotation. Wool was early a source of wealth and was famous in the 12th and 13th centuries. Salt is mentioned in Domesday as a product of the county; glass was made at Benson and Stokenchurch in the reign of Henry VI and other subsidiary products were plush at Banbury, leather at Bampton and Burford, gloves at Woodstock and malt at Henley. In the early 14th century, Oxford was the second most prosperous county in England, but the Black Death (1349) and decreasing arable land, the enclosures of the 16th century and the wars of the 17th brought depression and discontent, and on the enclosure of Otmoor (1830) serious riots broke out.

A high proportion of the county (about 81% in 1939) is under cultivation. Stock are raised on the clay lowlands, and dairying (Shorthorns, Alderneys and Devonshire cows) is important. The Cornbrash is specially good for grain growing, but crops of wheat, oats and barley have declined (75,225 ac. in 1939 compared with 91,049 ac. in 1926).

Sheep (Southdowns, Leicesters and Cotswolds) are still reared in large numbers on the uplands and are folded on the root crops (turnips, swedes, mangolds), which are important. The cultivation of sugar beet, which was flourishing in 1926 (1,196 ac.), later showed a serious decline but by 1939 had risen again to 859 ac.

Many pigs are reared and poultry do well on gravel sites. The county has few mineral resources; iron is obtained at various places; Oolitic limestone is quarried for cement, stone slates and, though less than formerly, for building stone. The clays are used for brickmaking and have been largely utilized for the building of the new town which has arisen around the motor industry at Cowley southeast of Oxford. The National Trust owned 380 ac. in the county in 1942.

Manufactures.—These are mainly those dependent on agriculture. Blankets are manufactured at Witney and tweeds at Chipping Norton. There are paper mills at Shiplake, Sandford-on-Thames, Wolvercot and Eynsham, using the pure water of the streams.

Agricultural implements and portable engines are made at Banbury, where there is also plush, shag and girth weaving. Gloves and polished steel are industries at Woodstock. Lace is made by country women. Banbury has been long celebrated for the manufacture of a peculiar cake.

Communications.—Many of the roads are ancient routes on the plateau or following the strike of the rocks, but the main railways are markedly transverse, linking London with the industrial northwest. The county is served entirely by the G.W. railway (except for a branch of the L.M.S. railway from Bletchley to Banbury and to Oxford). One main line from London passes through the Reading gap to Oxford, and here bifurcating, sends one line north along the Cherwell valley to Banbury and another across the northwest of the county, via the Evenlode valley, to link up with the Severn valley, Worcester and Birmingham; Kingham on the borders of Gloucestershire being a junction for a line west to Cheltenham (Glouc.) and a line northeast to King's Sutton (Northants). There are numerous branch lines.

Population and Administration.—The area of the administrative county, excluding the city and county borough of Oxford, is 736 sq.mi. with a population (est. 1938) of 135,200. Being an agricultural county and not far from London it was very suitable as a reception area for wartime evacuees, whose immigration between Sept. 1939 and Feb. 1941 raised the population by 21%. The municipal boroughs are Banbury, Chipping Norton, Henley-on-Thames, Oxford, a city and the county town, and Woodstock. The county is in the Oxford circuit and assizes are held at Oxford. It has one court of quarter sessions and is divided into 11 petty sessional divisions.

The borough of Banbury and the city of Oxford have separate courts of quarter sessions and commissions of the peace, and the borough of Henley-on-Thames has a separate commission of the peace. The total number of civil parishes is 233. The ancient county (which in 1289 sent two members to parliament) was divided in 1918 into two parliamentary divisions, Banbury and Henley, each returning one member.

It also includes part of the parliamentary borough of Oxford, returning one member, in addition to which the university of Oxford returns two members.

OXFORD UNIVERSITY. The stories connecting Oxford university with Brute the Trojan, with King Mempeic (1009 B.C.) and with the Druids, cannot be traced back beyond the 14th century. Authentic history appears to begin in 1133 with the arrival from Paris of the theologian, Robert Pullen, who lectured there. There is, however, little evidence that Oxford was regarded as a fully equipped university before 1163—allusions to its being a *studium generale* (*see* UNIVERSITIES) only occur after that date and these by some authorities are held to be inconclusive. Subsequent progress must, however, have been rapid as, about 100 years later, the deputies of Oxford, in an appeal to the king, described the university as *schola secunda ecclesiae* or second to Paris. The coming of the religious communities, the Dominicans, Franciscans and Carmelites in the 13th century and the Benedictines a little later, profoundly affected the advancement of learning. The names of Roger Bacon, John Duns Scotus and John Wycliffe are sufficient to indicate the prominence of Oxford in the middle ages. The earliest colleges to be founded were University college (1249; the mythical foundation by Alfred in 872 is no longer accepted), Balliol (about 1263) and Merton (1264). The latter was established to provide a collegiate discipline for the secular clergy, and its statutes served as a model for subsequent creations, not only at Oxford but at Cambridge.

From the 13th century onward a succession of charters from the crown strengthened the position of the university at the expense of the town. At the Renaissance the new learning found its leading exponents in Erasmus, who lectured there, and in such famous scholars as William Grocyn, John Colet and Sir Thomas More. The old scholasticism received its deathblow from the royal injunctions of 1535. Oxford, as well as Cambridge, suffered from numerous confiscations of land and revenues during the Reformation period. In 1571 the act of Elizabeth incorporated and reorganized the two universities. The statutes of the university were codified in 1636 by the chancellor Archbishop William Laud. With certain modifications, they formed the official code of the university until 1858. During the Civil War the university sided with the king, while the town sympathized with the parliament, but no open breach between the two occurred. Under Oliver Cromwell, who acted as chancellor from 1651 to 1657, an effort was made to restore the standards in work and discipline which had suffered from the civil wars. During the reign of James II, the university acquired popularity by its successful resistance to James's effort to open the university to Catholics, even to the extent of imposing his own Catholic nominee on the fellows of Magdalen. The university, however, soon returned to its Jacobite allegiance, and at the coming of the Georges was definitely anti-Hanoverian, a phase that came to an end after the visit of George III in 1785. In the latter half of the 18th century the influence of the Wesleys on Oxford was far less than on the country at large; on the other hand the Tractarian movement (*see* NEWMAN, JOHN HENRY), at the beginning of the 19th century, had a most profound effect on the Church of England, which re-

mained potent. There was a general rise in the level of studies toward the end of the 18th century as written examinations gradually supplemented the old oral examinations, often merely formal, and henceforth the range of studies themselves extended. By the reform of 1858 the professoriate was increased, reorganized and re-endowed, and dissenters were admitted to entrance to the B.A.—the M.A. being thrown open in 1871.

The reforms of 1877 directed a certain proportion of the college revenues to the use of the university (especially for the encouragement of natural science) and improved the position of professors and lecturers, thus leading to the growth of a regular resident professoriate. Schools and degrees alike multiplied (*see* UNIVERSITIES) and the history of the university was one of general progress and expansion.

Modern Oxford.—The beginning of the 20th century marked a turning point in university history because of the growth of scientific studies and of specialization in all studies.

In the 19th century the university had grown in size; the number of annual matriculations grew steadily, with a check between 1812 and 1849, from 240 in 1800 to 840 in 1900. Although the quality of teaching improved, the college fellows continued to provide practically the whole of the teaching and administrative strength of the university. This was possible because science made its way slowly. As late as 1900, out of 142 college tutors, only 21 (less than 15%) were scientists. There were in addition an equal number of science teachers paid wholly by the university. By 1940 the number of college tutors in science was 55 (including 4 women) out of 268 (more than 20%), and there were also 78 readers and demonstrators paid wholly by the university. Over the same period the number of science departments grew from 9 to 19. There had also been a considerable shift of interest among the undergraduates. In 1900 the number of candidates taking the final honours science examinations was only 47, or almost exactly 10% of the total number of candidates (469); in 1939 the candidates in science were 215 out of 1,305, or just over 17%. In the interval important new honours examinations in humane subjects had either developed (English had 4 candidates in 1900 and 120 in 1939) or had been introduced (modern languages had 123 candidates in 1939, and philosophy, politics and economics, 152). This swing from humane studies, which are taught didactically, to science which is taught by demonstration and experiment, mainly caused the growth in the significance of the university. Although five colleges had provided science laboratories, the possibility that science could be studied as a college activity was never really a serious one. Laboratories are common services and must be provided on a huge scale. Between 1900 and 1940 the annual expenditure on the science departments grew from £24,177 to £135,681.

These developments took place without the university's absorbing the colleges. Until after World War I the university depended on endowments, which in 1900 yielded £19,000 a year net, and on fees and dues, which brought in £30,488. Major developments were due to private benefactions. After World War I such sources ceased to be adequate, and in accordance with the recommendations of a royal commission, in the face of strong opposition within the university, a government grant was paid. This amounted in 1927–28 to 21% of the total expenditure. In 1938–39 the grants remained 21% (but the total expenditure was about 25% higher); in 1947–48 the grants were 49% and in 1948–49 they were 52%. The subsidizing of individual students out of public funds developed simultaneously, and in 1939 the proportion of students in receipt of some form of financial assistance was 55%.

The control of these growing resources, however, never passed into the hands of any body distinct from the colleges. What the framers of the Oxford constitution aimed at was to ensure that the university's business, being for the benefit of scholars, should be controlled by scholars. The effective power was thus vested in the university at large. Naturally it was primarily in the hands of those holding academic positions ("congregation"), but as late as 1919 the nonresident masters of arts were able to defeat a proposal for the abolition of compulsory Greek. In 1926 the nonresident masters were finally relieved of all but revising functions exercised if the university was internally divided; and since the nonresident masters number about 15,000 they could not in any case be an effective body. Power, therefore, rests with congregation (about 1,000 M.A.'s), all members of the separate colleges. The fact that all decisions affecting policy must be passed by congregation, in which it is always easy to stir up opposition, has prevented the university from imposing anything like bureaucratic control upon the colleges. Congregation has, indeed, only a limited power of initiation, its function being to pass judgment on proposals submitted to it by the Hebdomadal council, a body containing 5 ex officio members (the chancellor, vice-chancellor, the 2 proctors and a pro-vice-chancellor, who is either the outgoing or the incoming vice-chancellor) and 18 M.A.'s elected by congregation. The council is thus a body which exercises a great influence; but it is the influence of a leader in a free community who remains a leader only as long as anyone chooses to follow.

The passing of the powers of convocation (all M.A.'s), though inevitable, was regretted on account of the risk that the university would become a self-complacent community, unresponsive to changing public needs. Partly in order to make this risk less, the Oxford society was founded under the leadership of the then chancellor Viscount Grey of Fallodon in 1932. One of the objects of the society was to provide through its magazine a kind of forum, in which the residents would describe and justify to the nonresidents what they were doing.

Enrolment in World Wars I and II.—The contrast between the university's experience of World Wars I and II was striking. In World War I the young men were encouraged to enlist indiscriminately, and no attempt was made to use the resources of the university for war purposes, except that some of the buildings were used as hospitals or barracks. The number in residence (about 4,000 in Jan. 1914) by Jan. 1915 had fallen to 1,087. In 1917–18 the number fell to 460. In World War II all national resources were mobilized. Young men were ordered to remain at their universities until the services were ready for them. In consequence, the number of men at the university fell only from 4,147 in the Trinity term of 1939 to 2,761 in the Michaelmas term, and to 2,148 by 1940–41. Senior members of the university were also sent or kept where they would be most useful. Thus the university was never entirely denuded of active teachers and research workers.

Benefactions.—The university used to depend for developments upon private benefactors. The Bodleian library, the Sheldonian theatre, the Ashmolean Museum of Art and Archaeology, the Dyson Perrins laboratory, the Serena professorship of Italian, the Stanhope Historical Essay prize and other foundations commemorate the names of some of them. When World War I caused taxation to rise, the days of private benefactions seemed to have passed. Nevertheless, between 1930 and 1943 the university received (apart from Lord Nuffield's gifts to the medical school and Nuffield college, together amounting to £3,800,000; more than £500,000 from a special appeal; and the gifts of the Rockefeller foundation, notably £586,000 for the extension of the Bodleian library) gifts totalling £271,000 and annuities amounting to £2,795 a year: all this was apart from gifts in kind. World War II did not end the generosity of benefactors. In 1948 Antonin Besse gave £1,250,000 for the foundation of a new college, St. Antony's, and £250,000 for the expansion of the existing colleges. In addition a stream of smaller bequests continued to flow either to individual colleges or to the university.

List of Colleges and Halls.—University, Balliol and Merton have been mentioned above. The other colleges in their order of foundation are: Exeter (1314), Oriel (1326), Queen's (1340), New (1379), Lincoln (1427), All Souls (1438), Magdalen (1458), Brasenose (1509), Corpus Christi (1516), Christ Church (begun by Wolsey in 1525, final foundation by Henry VIII, 1546), St. John's (1555), Trinity (1555), Jesus (1571), Wadham (1612, charter received 1610), Pembroke (1624), Worcester (1714), Keble (1870) and Hertford (1874). (For further details *see* OXFORD.) Of the various academical halls, St. Edmund (reputed foundation, 1226) is the only one that survived. St. Peter's hall,

founded as a hostel in 1928, became a permanent private hall in 1929, and in 1947 was admitted by decree of convocation to the status of a new foundation (a status differing from that of a college mainly because the head does not become vice-chancellor, and the society does not make statutory contributions to the university; Keble had this status in 1950 though it was then applying to the privy council for incorporation as a college). In 1950 St. Antony's college was established with the status of new foundation. Nuffield college, founded in 1937, is peculiar in being a university institution and not an independent corporation. It is a postgraduate college intended "to encourage research especially but not exclusively in the field of social studies." There are also two private halls, Campion hall (1896) for members of the Society of Jesus and St. Benet's (1897) for Benedictines.

Noncollegiate students were admitted, as members of St. Catherine's society, in 1863. There are five women's colleges: Lady Margaret hall (1878), Somerville (1879), St. Hugh's (1886), St. Hilda's (1893) and St. Anne's (1952). St. Anne's was formerly known as the Oxford Society of Home Students.

Other Academic Buildings of Note.—Oxford possesses fine academic buildings. Some of the principal ones are the group of buildings comprising the Bodleian library, the Convocation house with the Sheldonian theatre and the Old Ashmolean museum, and the Radcliffe Camera not far away. The "university church" of St. Mary lies just to the south of the latter. Another group of buildings is devoted to the Taylor institute and the Ashmolean Museum of Art and Archaeology. Other important buildings are the university science laboratories which are grouped together on a site of about 17 ac., and the famous Clarendon press. Mention should also be made of the botanical garden by the River Cherwell and the Oxford Union society, founded in 1625. (*See* also OXFORD.)

University Constitution.—"The chancellor, masters and scholars of the University of Oxford" form a corporate body, within which the colleges are individual corporations. The highest officer of the university is the chancellor, who is elected by the members of convocation, holds office for life and is generally a distinguished member of the university. The vice-chancellor is in practice the head. He is nominated annually by the chancellor and must by convention be the senior head of a college who has not yet held this post and who is willing to accept it. Each vice-chancellor is nominated for three years in all. Two proctors (*q.v.*) are appointed annually by two of the colleges in rotation. Until 1950, when the privilege dating from 1604 was abolished, the university returned two members to parliament under a system of proportional representation.

The Hebdomadal council initiates and congregation decides the business of the university: but there is a considerable delegation of executive functions. The administrative work is assigned sparingly so that scholars can do it without affecting their scholarly work. The delegation ranges from such bodies as the curators of the Bodleian library, who spend about £85,000 a year, to such as the committee for classical archaeology which spends about £120.

The delegate bodies fall into two groups: (1) those (*e.g.*, faculty boards) dealing with academic questions, which maintain academic standards both by supervising the selection of the teaching and research staffs and their work, and by determining the content and standard of examinations—such bodies are supervised by the general board of the faculties; and (2) those which provide services not regarded as academic. To these, the curators of the university chest bear much the same relation as the general board does to academic delegacies. But the curators are also responsible for advising the Hebdomadal council on financial matters, for managing the real property and other investments of the university and for ensuring that accounts are so kept as to form a trustworthy basis for estimating future expenditure and detecting waste.

The colleges consist of a head, whose title varies in different colleges, fellows (who form the governing body) and scholars. To these are to be added the commoners; *i.e.*, those who either receive no emoluments, or hold exhibitions which do not generally entitle them to rank with the scholars. The college officer who is immediately concerned with the disciplinary surveillance of members of the college *in statu pupillari* is the dean (except at Christ Church). Each undergraduate (this term covering all who have not yet proceeded to a degree) is, as regards his studies, under the immediate supervision of one of the fellows as tutor.

Degrees.—Nobody can study for a degree or be a member of the university unless he is a member of a college. The examinations for the B.A. (the title of the first degree, no matter in what subject it is taken) are: (1) responsions—an entrance examination taken before coming into residence (various other examinations of comparable standard are accepted as its equivalent); (2) the first public examination which may be an honours examination in Greek and Latin literature, or in mathematics or science (four subjects), or a pass examination designed as a preliminary to one of the final honour schools; (3) the second public examination which may be either an honours examination in a single subject or in two or three closely related subjects (a final honour school), or a pass examination in three unrelated subjects. In addition there are examinations in theology (for the B.D. degree), law (for the B.C.L.), medicine (for the B.M., and B.Ch.) and music (for the B.Mus.), which are normally taken after the B.A. Degrees of B.Litt., B.Sc. and D.Phil. are awarded for original research undertaken under supervision, and the higher doctorates for published work containing an original contribution to the advancement of learning.

OXIDATION AND REDUCTION are chemical terms applied to changes in the electrical charge of an element in the course of a chemical reaction. For example, the combination of sodium and chlorine involves the transfer of an electron from a sodium atom to a chlorine atom and the formation of a sodium-chloride molecule in which the sodium is charged positively and the chlorine negatively, (Na^+) (Cl^-). The element which has lost electrons and thus acquired positive charges is said to be oxidized and the process is called oxidation. The element which gained electrons is reduced and the process is one of reduction. Thus, the combination of sodium and chlorine is an oxidation-reduction reaction resulting in the oxidation of the sodium and the reduction of the chlorine. In this reaction the chlorine is the oxidizing agent and the sodium the reducing agent.

Before the introduction of the electron concept, the term oxidation was applied to reactions in which an element gained oxygen as in the burning of carbon, $C + O_2 = CO_2$, or the rusting of iron, $4Fe + 3O_2 = 2Fe_2O_3$; the term reduction designated a reaction by which an element lost oxygen, such as the reduction of copper oxide by hydrogen, $CuO + H_2 = Cu + H_2O$.

In all oxides, the oxygen atom has a charge of -2 (or oxidation number of -2); hence, when free oxygen gas combines with another element to form an oxide, it gains electrons from that element.

In the generalized concept the term oxidation has been extended to include all similar reactions.

Many substances in water solution ionize (that is, dissociate into their charged constituents; *e.g.*, $NiCl_2 = Ni^{++} + 2Cl^-$), and the electrolysis of such solutions results in an oxidation process at the anode and a reduction at the cathode. For the electrolysis of $NiCl_2$ the anode reaction is $2Cl^- = Cl_2 + 2e^-$ and the cathode reaction $Ni^{++} + 2e^- = Ni^{++}$. These reactions involving the electrons are called half reactions or oxidation-reduction couples. Each couple has the reduced state of the element as one half and the oxidized state plus electrons as the other half. In theory, every oxidation-reduction reaction may be broken up into two couples which indicate the mechanism by which electrons are transferred. $Ag + 2HNO_3 = AgNO_3 + NO_2 + H_2O$; couples, $Ag + NO_3^- = AgNO_3 + e^-$ and $e^- +$

$2HNO_3 = NO_2 + NO_3^- + H_2O$. From this mechanism it is evident that oxidation and reduction occur simultaneously and in equivalent amounts; *i.e.*, the number of electrons lost is equal to the number gained. The relative potentials of the two couples determine the direction in which the reaction will proceed (*see* THERMODYNAMICS).

The most powerful reducing agents are the electropositive metals such as sodium. These readily reduce the compounds of the noble metals and also liberate hydrogen from water: $AgCl + Na = Ag + NaCl$ and $2Na + 2H_2O = 2NaOH + H_2$. The noble metals are poor reducing agents but their compounds are good oxidizing agents. Among the most powerful oxidizing agents are fluorine, ozone and cobaltic ion. These readily liberate oxygen from water, $F_2 + 2H_2O = O_2 + 2HF$. Hydrogen peroxide, potassium permanganate and ceric compounds are examples of powerful oxidizing agents which are used extensively in analytical and industrial chemistry. (W. M. LA.)

OXIDE, in chemistry, a binary compound of oxygen and another element. Oxides are the most plentiful and characteristic components of the earth's hydrosphere and lithosphere: the hydrosphere consists essentially of water, the commoner oxide of hydrogen; and the lithosphere of simple oxides of the general formula A_mO_n and complex oxides of the type $A_xB_yC_z \ldots O_n$. The complex oxides are more abundant, and the study of them forms the greater part of mineralogy, since they include many important rock-forming materials. Work on the structure of crystals has shown that the former inclusion of carbonates, aluminates and aluminosilicates among the complex oxides was not strictly correct (*see* below), though their empirical formulas are often given as though they consisted of oxides; *e.g.*, beryl, $Be_3Al_2Si_6O_{18}$, which is a silicate, may be written incorrectly as $3BeO.Al_2O_3.6SiO_2$. The ordinary ingredients of soil, subsoil and rocks are partly composed of oxides in either anhydrous or hydrated forms.

Oxygen can be made to combine directly with most elements, although sometimes it will not do so in the entire absence of water vapour (*see* DRYNESS, CHEMICAL); in a few cases in which direct methods are unavailing, as, for example, in the case of noble metals such as gold or platinum which remain unaffected in air even at very high temperatures, indirect methods can be used and oxides can be prepared from the salts of the metals. Oxides of the inert gases (helium, neon, argon, etc.) do not exist and would not be expected on modern theories of chemical bond-formation. Fluorine and later bromine (1930–40) have been oxidized by special methods, but for a long time it was thought that they would not form oxides.

Many elements form a series of several oxides. Thus nitrogen yields six: N_2O, NO, N_2O_3, NO_2 (N_2O_4 at lower temperatures), N_2O_5 and possibly NO_3. In general, the acidic character of the oxide increases with increase in the oxygen content. For purposes of classification it is usual to assign a typical oxide to each element; usually this oxide is the highest having acidic or basic properties and is related to the position of the element in the periodic classification (*see* PERIODIC LAW) as follows: the typical oxides of Group I are of the form M_2O[I], (roman numeral in brackets indicates periodic group) of Group II those of the form MO[II], of Group III those of the form M_2O_3[III], and so on, Group VI being those of the form MO_3[VI]. The oxides of typical metals (*e.g.*, MgO) are known to be aggregates of oxygen ions (O'') and positive metal ions held together by electrostatic forces in certain geometrical arrangements, while oxides of nonmetals (*e.g.*, CO_2) are usually volatile compounds, the constituent atoms being held together by covalent bonds. Less electropositive metals will form chemical bonds with oxygen which will have considerable covalent nature; *e.g.*, PtO.

Types of Oxide.—Oxides are often classed as (1) acidic oxides; (2) basic oxides; (3) amphoteric oxides; (4) neutral oxides; (5) suboxides; (6) higher oxides including peroxides, superoxides and dioxides or polyoxides; (7) mixed oxides; and (8) complex oxides. An oxide may not fall clearly into any one of these classes but have the characteristics of two.

1. Acidic oxides are those which combine with bases or basic oxides to form salts. Many of the oxides of nonmetals (*e.g.*, carbon, nitrogen, phosphorus and sulphur) are of this type. Some acidic oxides are "mixed" anhydrides: thus nitrogen peroxide reacts with water to give two acids, nitrous and nitric, and with bases to form nitrites and nitrates.

2. Basic oxides similarly react with acids or acidic oxides to form salts, and many of the oxides of metals fall into this class.

3. Amphoteric oxides behave as acidic oxides toward bases and as basic oxides toward acids: thus zinc and aluminum oxides dissolve in acids or bases to give salts of the acid or zincates (aluminates) of the base, respectively.

4. Neutral oxides are those which neither react to form salts nor combine with water to give acids or bases: carbon monoxide and nitrous oxide are examples, for although they result from formic and hyponitrous acids, respectively, by loss of water, they do not combine with water to give these acids and are therefore not acidic anhydrides.

5. Suboxides have less oxygen than the common lowest stable oxide, but the term is often loosely used. Carbon suboxide (C_3O_2) is one of the few true suboxides and is obtained by the dehydration of malonic acid, into which it can be converted again by water. At 200° C. carbon suboxide can be changed into a lower oxide, pentacarbon dioxide, C_5O_2. Some so-called suboxides (*e.g.*, lead suboxide, Pb_2O) are now considered to be mixtures (in this case, of lead and lead monoxide). Certain metals, particularly titanium, will yield solid oxides slightly deficient in oxygen or metal and are therefore nonstoichiometric; *i.e.*, they do not obey the law of constant composition. Such "deficient" oxides often show special electrical conductivity properties.

6. Higher oxides have more oxygen than the typical oxide as determined by the periodic classification and can be divided mainly into three groups: (*a*) peroxides, (*b*) superoxides and (*c*) dioxides.

a. Peroxides contain two oxygen atoms linked together to form the grouping $-O-O-$ and usually occur in solid oxides as O''_2 ions. They are closely related to hydrogen peroxide (a neutral oxide), and the latter is formed when peroxides are treated with water or dilute acid. True peroxides are formed by metals such as sodium and barium (*e.g.*, Na_2O_2 and BaO_2). The peroxide link is also found in certain peracids (*e.g.*, persulphuric acid, $H_2S_2O_8$) and their salts. Many organic compounds can have the oxygen atom replaced by the $-O-O-$ group, and these are known as organic peroxides (*e.g.*, diethyl peroxide, $C_2H_5-O-O-C_2H_5$). They are not very stable and can be used, like other peroxides, as powerful oxidizing agents. The formation of peroxides in the oxidation of gasoline in the internal combustion engine is well known, and diethyl peroxide is a "pro-knocking" agent.

b. The final oxidation products (KO_2) of potassium are known to contain the superoxide ion $(-O-O-)^-$; such compounds, formerly known as tetroxides and written as M_2O_4[I], are called superoxides.

c. Certain other oxides, often termed peroxides, are of an entirely different type from true peroxides and contain the ordinary oxygen ion (O'') linked to the metal ion. Thus lead peroxide is now called lead dioxide since it shows no structural similarity with a true peroxide, but it is, of course, a strong oxidizing agent. Like manganese dioxide it reacts with an acid to give a salt of lower valency, *e.g.*, MnO_2[IV] $+ 4HCl = MnCl_2$[II] $+ Cl_2 + 2H_2O$, but not hydrogen peroxide.

The typical oxides of Group VII elements, Cl_2O_7 and Mn_2O_7, are not peroxides, but S_2O_7 (if it exists) would have more oxygen than the typical oxide of sulphur (SO_3 in Group VI) and might be expected to have some of the properties of a peroxide.

7. Metals that have two valencies can form oxides containing the metal in its two different valencies (*e.g.*, Pb_3O_4 and Fe_3O_4), and these mixed oxides will have some resemblance to complex oxides (*see* below). Thus Pb_3O_4 has been shown to have a crystal structure consisting of chains of tetravalent lead ions surrounded octahedrally by oxygen ions with divalent lead ions linking the chains together. The action of acids upon such an oxide will yield a mixture of compounds derived from Pb[II] and Pb[IV]: thus $Pb_3O_4 + 2HNO_3 = PbO_2$ [IV] $+ Pb(NO_3)_2$[II].

8. Complex oxides can be divided into two large groups: (*a*) those which contain oxyions (CO_3'', SiO_3'', etc.) and are more

strictly known as oxysalts rather than oxides; and (*b*) those which consist of aggregates of oxygen ions (O'') and positive metallic ions and are true complex oxides.

The latter will have different geometrical arrangements in their crystal form according to the relative sizes and numerical proportions of the constituents. As the oxygen ion is usually much larger than the metallic ion, there will be a close packing of the negative oxygen ions with the positive ion or ions occupying the interstices between the oxygen ions.

Metals of the same size will yield complex oxides of similar crystal structure, since it is possible to replace one metal by another of a similar size: thus, in the spinels of general formula MAl_2O_4, the metal M can be Fe, Co, Ni, Mn or Zn, yielding a whole series of spinels. Where the metallic ion approaches the size of the oxygen ion a new geometrical arrangement will be necessary, and there are a number of possible structures; typical of these is the perovskite structure of the so-called titanates, $SrTiO_3$, etc., in which the large Sr^{2+} or Ba^{2+} ions are closely packed with oxygen ions, and the smaller Ti^{4+} occupies the interstitial positions. The study of such structures is an important aspect of inorganic chemistry (for fuller details *see* A. F. Wells, *Structural Inorganic Chemistry*, Oxford, 1951). The production of artificial minerals such as sapphires for use as bearings is an interesting industrial process. Mixtures of metallic oxides and oxides of metals with variable valency such as vanadium are of great importance in modern catalytical chemistry, for example, in the manufacture of sulphuric acid.

Many oxides combine with water to form hydroxides (*see* HYDROXIDE), and all hydroxides lose water on heating to give the corresponding oxide. The chemical properties of a hydroxide are almost identical with those of the corresponding oxide, but the latter is somewhat more inert, especially if it has been very strongly heated.

For further details *see* OXIDATION AND REDUCTION; *see* also H. B. Weiser, *The Hydrous Oxides*, "International Chemical Series" (1926).
(A. D. M.; F. H. P.)

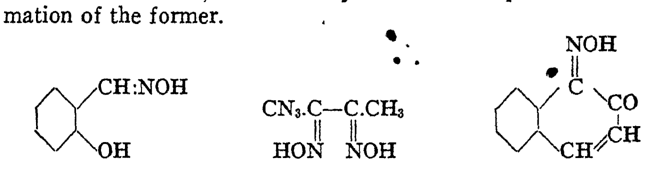
OXIMES are organic compounds containing the group >C:NOH. They are obtained either by the action of hydroxylamine on an aldehyde or ketone (I), or by the action of nitrous acid or its esters on a compound containing a reactive methyl or methylene group (II). The products of the latter type of reaction are sometimes called isonitroso compounds, but they are all true oximes and the prefix oximino is better than isonitroso.

$$\underset{\text{I}}{>C{:}O + H_2NOH \rightarrow} >C{:}NOH + H_2O \leftarrow \underset{\text{II}}{>CH_2 + O{:}NOH.}$$

Victor Meyer prepared the first oxime in 1878 and since that date the compounds have been of continued interest to organic chemists because of their value in identification and synthesis and still more so because of the stereoisomerism which occurs in certain classes of oximes (*see* STEREOCHEMISTRY).

Oximes are usually regarded as derivatives of aldehydes and ketones and thus are divided into aldoximes and ketoximes. Since they are solids which, apart from the simplest members, are insoluble in water and crystallize well, they are used to some extent for isolating and identifying aldehydes and ketones. The rate of oxime formation, however, is often somewhat slow, so that it is frequently more convenient to use derivatives of hydrazine. The oximes behave as weak acids and also as weak bases. They are reduced to primary amines, and this is a useful method for effecting the change $>CO \rightarrow >CHNH_2$. The aldoximes are dehydrated to nitriles by acid chlorides or anhydrides, $-CH{:}NOH \rightarrow -CN + H_2O$, a reaction which was of value in the early study of the structures of the simpler sugars. All oximes can be hydrolysed by aqueous mineral acids, with varying ease, to the parent aldehyde or ketone and hydroxylamine, but they are stable to aqueous alkalies. The characteristic reaction of ketoximes, the Beckmann transformation, is discussed below.

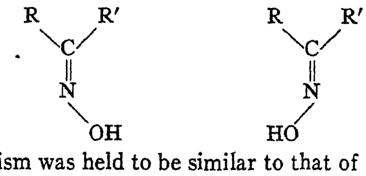
Certain oximes form stable co-ordination compounds with metals and since there are marked differences in the solubilities of the oxime complexes of closely related metals, these oximes are valuable quantitative reagents in analytical chemistry. Three examples will be given. Salicylaldoxime (III) forms complexes with a variety of metals, but they are all soluble in dilute acetic acid except that of copper. The latter is a greenish-yellow powder which can be dried at 110° C. without decomposition. Hence F. Ephraim introduced this oxime as a reagent for the quantitative separation and determination of copper. Dimethylglyoxime (IV), the dioxime of a diketone, forms a series of complexes with metals of which only those with nickel and palladium are insoluble in dilute alkalies and weak acids. It is, therefore, the standard reagent for determining these metals and, in particular, gives a quantitative separation of nickel from cobalt. Finally, β-naphthaquinone monoxime (V) forms an insoluble complex with cobalt but not with nickel, and is widely used for the quantitative estimation of the former.



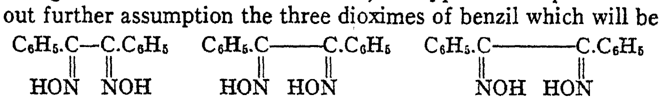
III IV V

Stereochemistry of the Oximes.—From the point of view of the development of stereochemistry, the oximes are of great interest. In 1883 Hans Goldschmidt found that the dioxime of benzil ($C_6H_5.CO.CO.C_6H_5$) existed in two forms, and a third form was obtained by Victor Meyer in 1889. In the same year Ernst Beckmann found that an aldoxime, that of benzaldehyde, existed in two forms. Geometrical isomerism in unsaturated carbon compounds had already been recognized by J. H. van't Hoff and generally accepted, and in 1890 Arthur Hantzsch and Alfred Werner extended this conception to compounds containing the group >C:N— and advanced the view that these isomeric oximes were geometrical isomers. This view is now known to be true, but it was not accepted by all at first and the ensuing controversy led to much experimental work which laid a solid foundation for fundamental knowledge in a wide field of stereochemical problems.

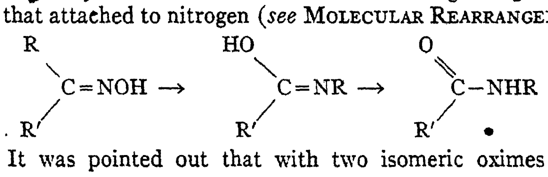
The Hantzsch-Werner hypothesis was that the oxime of an unsymmetrical ketone or of an aldehyde can exist in two forms which may be written:



The isomerism was held to be similar to that of compounds containing the group >C:C<, as with maleic and fumaric acids. The hypothesis implies two postulates: (1) that the hydroxyl group is not placed symmetrically with respect to the carbon and nitrogen atoms, but lies to one side of the line joining them; (2) that there is no "free rotation" about the double bond between the carbon and nitrogen atoms, so that the two forms are not readily interconvertible. There were three weighty reasons for the hypothesis. First, isomeric oximes should, and in fact do, occur only when the groups R and R′ are different; *i.e.*, in aldoximes and oximes of unsymmetrical ketones. If R and R′ are alike, the two configurations are identical. Second, the hypothesis explains without further assumption the three dioximes of benzil which will be:



The last argument was based on the Beckmann transformation of the ketoximes. This occurs when a ketoxime is treated with certain acidic reagents, notably phosphorus pentachloride in dry ether. The product obtained after treatment with water is a substituted acid amide. There must be an exchange of groups, one originally attached to the carbon atom having changed places with that attached to nitrogen (*see* MOLECULAR REARRANGEMENTS).



It was pointed out that with two isomeric oximes of formula

RR′C:NOH, the main product obtained from one isomer is the amide R′CO.NHR, whereas the other gives the isomeric amide R.CO.NHR′. This is strong evidence that the isomeric oximes have the same structure but a different space arrangement.

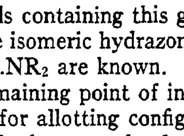
Many more facts later accumulated to support the view of Hantzsch and Werner and show that geometrical isomerism occurs in the oximes. Reference can be made to only a few. The opposing view was that the isomerism is structural and not geometrical, and was based on the structural differences which are possible in the oxime grouping. For example, oximes form two series of ethers, in one of which the alkyl group is attached to oxygen and in the other to nitrogen. Several cases are, however, now known where not only the oxime but also its O— and N— ethers have been obtained in isomeric pairs, all distinct crystalline solids. This shows that the isomerism survives minor changes in structure.

The truth of postulate (1), the unsymmetrical position of the hydroxyl group, was established by the ingenious and beautiful experiments of W. H. Mills (1910–31). In this work the aim was to prepare a compound which, if the postulate is correct, has a space configuration not superposable on its mirror image, so that it should exist in optically active forms, whereas, if the postulate is incorrect, resolution into optically active forms is impossible. Several such compounds have been resolved, and in one of them (Mills and B. C. Saunders, 1931) the molecule is such that the optical activity cannot arise from any other cause, probable or improbable, than the unsymmetrical position of the group attached to nitrogen in >C:N—. A final argument which should be given is that if the isomerism is geometrical, it should occur in compounds containing this group other than the oximes. This is true, since isomeric hydrazones containing the group >C:N.NHR or $>C:N.NR_2$ are known.

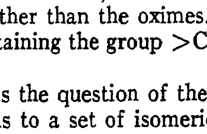
The remaining point of interest is the question of the methods available for allotting configurations to a set of isomeric oximes. Such methods must clearly be based on reactions in which the isomers differ. Hantzsch and Werner pointed out that such reactions are known and applied them to this purpose. With aldoximes the acetyl derivatives of an isomeric pair differ in that one, when treated with aqueous sodium carbonate, is hydrolysed to the oxime, whereas the other eliminates acetic acid and gives a nitrile. If it is assumed that this elimination of acetic acid takes place with the oxime in which the acetyl and hydroxyl groups are on the same side of the double bond, the configurations follow:

$$\begin{array}{l}\text{R.C.H}\\ \quad\|\\ \text{NOAc}\end{array} \longrightarrow \text{RCN} + \text{AcOH} \qquad \begin{array}{r}\text{R.C.H}\\ \|\quad\\ \text{AcON}\end{array} \longrightarrow \begin{array}{r}\text{R.C.H}\\ \|\quad\\ \text{HON}\end{array}$$

Similarly with the ketoximes, they pointed to the two products of the Beckmann transformation mentioned above and allotted configurations on the assumption that groups situated on the same side of the double bond (often described as in the syn-position) exchange places. Doubts as to the validity of the two assumptions made in these arguments were expressed as early as 1904 (P. Pfeiffer), but the matter came to a head in 1921 when J. Meisenheimer published results showing that the oxidation with ozone of the compound shown in (VI) gives a derivative of β-benzilmonoxime and the latter must thus have the configuration corresponding to (VII). On the assumption of Hantzsch and Werner, however, this is the configuration of the α-monoxime.



VI



VII

This discovery led to an extended series of investigations both in Germany and England, the aim being to establish the configuration of an oxime by some indisputable method, so that the validity of the original assumptions could be settled. One of the most brilliant of these studies was that of Meisenheimer in 1932 in which appeal was made to an entirely different set of phenomena, the occurrence of optical activity in certain naphthalene compounds because of interference to free rotation about a single link by the close packing of groups. All results tended to show that the original assumption was wrong and that groups in the anti-position, and not the syn-, are involved in the Beckmann change. This was confirmed, and the matter put beyond doubt, when methods became available for measuring certain physical properties of an isolated molecule. Arguments from physical properties had carried little weight so far because the properties considered were those of an assembly of molecules and the issue is obscured by the interactions between molecules. The measurement of the molecular electric moments of the N-methyl ethers of *p*-nitrobenzophenone oxime by T. W. J. Taylor and L. E. Sutton in 1931 showed a large difference which can arise only from the fact that the groups making the main contribution to the moment, the nitro group and the bond between nitrogen and oxygen, are so arranged that their effects are opposed in one isomer while in the other they have a component in the same direction. This result was decisive and the configurations now allotted are the reverse of those put forward originally. In a somewhat similar way the configurations of the aldoximes have also been settled, and it is known that elimination of acetic acid in an acetyl derivative involves the groups lying across, and not on the same side of, the double bond.

Many points in oxime chemistry remained obscure at mid-20th century, notably the reason why only a limited number of oximes occur as geometrical isomers out of the large number which might be expected to do so. (T. W. J. T.)

OXNARD, a city of Ventura county, California, U.S., on the Southern Pacific railway, midway between Los Angeles and Santa Barbara, and 4 mi. from the ocean. The population in 1950 was 21,567; in 1940 it was 8,519 by federal census. It is the trading centre for an extensive agricultural district, and has a large beet-sugar factory and other industries. It is the hub of the harbour of Port Hueneme. Oxnard was founded in 1898 and incorporated in 1903.

OXUS or AMU DARYA, one of the great rivers of central Asia. From Lake Victoria (Sor-Kul) in the Pamirs, which was originally reckoned as the true source of the river, to Khamiab, on the edge of the Andkhui district of Afghan Turkistan, for a distance of about 680 mi., the Oxus forms the boundary between Afghanistan and the U.S.S.R. For another 550 mi. below Khamiab it follows an open and sluggish course till it is lost in the Aral sea. The level of Lake Victoria is 13,400 ft. above sea. At Khamiab the river is probably less than 500 ft. The total length of the river is 1,500 mi. and its catchment area about 116,000 sq.mi. The annual rainfall of this basin varies probably between 10 to 20 in., and its discharge into the Aral sea is about 35,000 cu.ft. per second. About 2,300 sq.mi. depend on its waters for irrigation.

Sources.—The final survey of the Pamir region (wherein the heads of all the chief tributaries of the river lay hidden), by the Pamir boundary commission of 1895 established the following facts. The elevated mountain chain, called the Nicolas range, which divides the Great from the Little Pamir, is a region of vast glaciers and snow fields, supplying the greater part of the water of the lakes lying immediately north and south. The Nicolas range may be regarded as the chief fountainhead, through Victoria and Chakmaktin lakes, of at least two of the upper tributaries of the Oxus, namely, the Aksu (or Murghab) and the Pamir river, and as contributing largely to a third, the Ab-i-Panja. The enormous glaciers which lie about the upper or main branch of the Ab-i-Panja (called the Ab-i-Wakhjir or Wakhan), which rises under the mountains enclosing the head of the Taghdumbash Pamirs are an important source of the river.

Kala Panja to Ishkashim.—From the point where the rivers of the Great and Little Pamirs join at Kala Panja to Ishkashim, at the elbow of the great bend of the Oxus northward, the river valley and the northern slopes of the Hindu Kush, which near Ishkashim extend in slopes of barely 10 mi. in length from the main watershed to the river banks, were carefully mapped. These slopes represent the extent of Afghan territory which exists north of the Hindu Kush between Kala Panja and Ishkashim. From Ishkashim northward the river passes through the narrow rock-bound valleys of Shignan and Roshan, then north and west through the mountains and defiles of Darwaz. This part of the Oxus, until it once again emerges from the Bokhara hills into

the open plains bordering Badakshan on the north, fell within the area of Russian surveys.

Eighty-five miles north of Ishkashim, at Kala Wamar, the river which rises in the Little Pamir, and which is called Aksu, Murghab, or Bartang, joins the Oxus from the east. At this point the measurement of the comparative lengths of the chief Pamir tributaries of the Oxus is as follows: to the head of the Aksu at Lake Chakmaktin 260 mi.; to the head of the most easterly tributary of Lake Victoria, in the Great Pamir, about 230 mi.; to the glacial sources of the Ab-i-Wakhjir, about 230 mi. For 120 mi. the two latter are united in the main stream of the Oxus, the volume of which has been further increased by the Ghund and Shakhdara draining the Alichur Pamir and the heights of Shignan.

Ishkashim to Kolab.—The narrow cramped valley of the river between Ishkashim and Kala Wamar is hedged in on the west by a long ridge flanking the highlands of Badakshan; on the east the buttresses and spurs of the Shignan mountains (of which the strike is transverse to the direction of the river and more or less parallel to that of the main Hindu Kush watershed) overhang its channel like a wall, and afford but little room either for cultivation or for the maintenance of a practicable road. Yet the lower elevation (for this part of the Oxus stream is not more than about 7,000 ft. above sea level) and comparatively mild climate give opportunities to the industrious Tajik population for successful agriculture.

Beyond the Bartang (or Murghab) confluence the valley narrows, and the difficulties of the river route increase. Between Kala Wamar (6,580 ft.) and Kala Khum (4,400 ft.), where the Oxus again bends southward, its course to the northwest is almost at right angles to the general strike of the Darwaz mountains, which is from northeast to southwest, following the usual conformation of all this part of high Asia. Thus its chief affluents from the northeast, the Wanj and the Yaz Ghulam, drain valleys which are comparatively open. At Kala Khum the river is 480 ft. wide, narrowing to 350 ft. in the narrowest gorge. Its level varies with the obstructions formed by ice, falling as much as 28 ft. when its upper channels are blocked.

In the valleys of the Waksh and the Surkhab to the north of Darwaz, which form an important part of the province of Karategin, maple, ash, hawthorn, pistachio and juniper grow freely in the mountain forests, and beetroot, kohl rabi and other vegetables are widely cultivated. About the cliffs and precipices of the Panja valley near Kala Khum are the wild vine, cerasus and pomegranate, and the plane tree and mulberry flourish in groups near the villages. There also, among other plants, the sunflower decorates village gardens. The river's left bank belongs to Afghanistan.

From Kala Khum the river follows a southwesterly course for another 50 mi. through a close mountainous region and widens into the more open valley to the south of Kolab.

The topography of Darwaz south of the river is not accurately known, but at least one considerable stream of about 60 mi. in length, drains to the northeast, parallel to the general strike of the mountain system into the transverse course of the Oxus, which it joins nearly opposite to the lateral valleys of Yaz Ghulam and Wanj. This stream is called Pangi-Shiwa, or Shiwa. Another of about equal length, the Ragh or Sadda, starting from the same central water-parting of this mountain block, and included within the Oxus bend, follows a transverse direction at almost right angles to the Shiwa, and joins the Oxus valley near its mouth into the more open Kolab plains, where the course of the Oxus has again assumed a direction parallel to the mountain strike. Toward its junction with the Oxus it cuts through successive mountain ridges, which render its course impracticable as a roadway. To avoid the river, and to pass by mountain tracks which surmount a series of local spurs or offshoots from the central plateau, in order to reach the Oxus, an important route, traversing the Darwaz mountains from east to west, cutting off the northern bend of the Oxus, and connecting those easterly routes which intersect the Pamirs by means of the Ghund and Shakhdara (and which concentrate about Lake Shiwa) with Kolab in eastern Bokhara, was developed.

(*See* BADAKSHAN.)

Badakshan Region.—From about the point where the Oxus commences to separate Russian territory from the comparatively open Afghan districts of Rustak and Kataghan, it adopts an uncertain channel and splits, leaving broad central islands. Besides the Kolab and Surkhab (or Waksh), the great muddy affluents from Karateghin on the north—the Kabadian, the Surkhan, and the Darbant—are very considerable tributaries from Bokhara. The last is the river on which the well-known trade centre of Shirabad is built, about 20 mi. north of the river.

From the south the Kokcha and the Khanabad (or Kunduz) join the Oxus between Kolab and the Mazar crossings. The valley of the Kokcha leads directly from the Oxus to Faizabad, the capital of Badakshan, and its head is close above Ishkashim at the southern elbow of the great Oxus bend, a low pass of only 9,500 ft. dividing its waters from those of the main river. This undoubtedly was a section of the great central trade route of Asia, which once connected Ferghana and Herat with Kashgar and China. (*See* BADAKSHAN.) This river and the Khanabad tap the northern slopes of the Hindu Kush; their sources are in the Kafiristan mountains.

To the west of the Kunduz no rivers find their way through the southern banks of the Oxus. Throughout the plains of Afghan Turkistan the drainage from the southern hills is arrested and lost in the desert sands.

The left bank above Kilif is, as a rule, low and flat, with reed swamps and a strip of jungle between the reeds and the edge of the elevated sandy desert. The jungle is chiefly tamarisk and padah (willow). Swamp deer, pheasants and occasionally tigers are found in it.

The right bank is generally higher, drier, more fertile and more populated than the left.

Irrigation.—A wide belt of blown sand (or Chul), sprinkled with saxaul jungle, separates the swamps on the south side of the river from the cultivated plains of Afghan Turkistan; but in places, notably for about 12 mi. above Khamiab where the Russo-Afghan boundary touches the river, through the Khwaja Salar district and in a less degree for 50 mi. above the Kilif ferry, the Ersari Turkman repelled the encroaching desert sand-waves, and a strip of riverain soil averaging about a mile in width was reclaimed and cultivated by irrigation. The cultivation, principally of wheat and barley, supported by canals drawn from the Oxus (the heads of which are constantly being destroyed by flood and again renewed) is of a very high order. The fields are intersected by narrow stone-walled lanes, bright with wayside flowers, among which the poppy and the purple thistle of Badghis are predominant; the houses, neatly built of stone, are scattered in single homesteads, substantial and comfortable; and the willow and mulberry offer a grateful shade in summer, when the heat is often insupportable.

The fiery blasts of summer, furnace-heated over the Kizil Kum, are hardly less to be feared than the ice-cold northwestern blizzards, which freeze men in the open desert, and frequently destroy whole caravans.

Below Khamiab, to its final disappearance in the Aral sea, the Oxus flows through a vast expanse of sand and desert. Under Russian auspices a considerable strip of alluvial soil on the left bank was brought under cultivation; however, cultivation is confined to the immediate neighbourhood of the river, for no affluents of any considerable size exist. The river is navigable below Charjui.

About 100 mi. above the Aral sea is the ancient oasis of Khwarezm or Khiva, entirely dependent on the Oxus for irrigation. The river there perpetually shifts eastward, causing a constant need for lengthening the irrigation channels lest the oasis become a desert.

OXY-ACETYLENE BLOWPIPE. An apparatus with a mixing jet which produces an intensely hot flame by projecting and burning acetylene with oxygen. It is of great value for metal-working, producing a flame which attains about 6,000° F. at the hottest part. In the high-pressure system, which is best for portable outfits, both the acetylene and the oxygen are delivered under pressure to the blowpipe, both from cylinders. In the

low-pressure system the acetylene is drawn direct from a generator. The blowpipes are manipulated either by hand, or guided in a machine. They are used for cutting out various shapes, parting thick sections, cutting out pieces for repairs or breaking-up purposes or welding to make new articles, and for various other purposes. When used for cutting, a separate jet of cutting oxygen is provided. This oxidizes or burns the hot metal. The oxide or "rust" thus formed is removed by the force of the jet and a cutting effect results.

When used for welding theoretically the welding flame should be neutral, that is, there should be no excess of acetylene or oxygen but in practice a little more oxygen than acetylene is used. Parts can also be heated conveniently for bending or straightening, and glass can be heated for working. The oxy-acetylene flame is too hot for brazing purposes, for which an oxy-coal-gas blowpipe has to be used. The approximate temperature of the oxy-acetylene flame may be compared with those of other flames from the following figures: Oxy-acetylene, 4,400° C; oxy-hydrogen, 2,420°; oxy-coal-gas, 2,200°; air-acetylene, 2,500°; air-coal-gas, 1,800°. (*See* WELDING.)

OXYGEN, a colourless, odourless, tasteless gas, somewhat heavier than air (sp.gr. 1·10523); it is slightly soluble in water. and this dissolved oxygen plays an essential part in the respiration of aquatic animals. (Symbol O, atomic number 8, atomic weight 16·000.) Oxygen combines with nearly all the elements under suitable conditions, but these reactions often do not take place if the substances are perfectly dry. With the exception of the "noble" metals, gold and the platinum group (*q.v.*), the metallic elements all oxidize when heated in oxygen, although molten silver dissolves 22 volumes of the gas without combining chemically with it, the absorbed oxygen escaping again when the metal cools.

Oxygen is by far the most abundant element, being nearly equal in amount to all the others put together. It forms 21% by volume of the atmosphere, eight-ninths by weight of water, and nearly one-half by weight of all the rocks composing the half-mile crust of the earth. Growing plants absorb carbon dioxide (*see* CARBON, OXIDES OF), assimilating carbon and rejecting oxygen. It is the only gas able to support respiration.

Preparation and Properties.—It is readily prepared on a small scale by heating a mixture of potassium chlorate with about one-third of its weight of manganese dioxide, which facilitates the decomposition. From 1886, for about 20 years, oxygen was produced commercially by the Brin or barium oxide process. Barium monoxide was heated to 1,000° F and absorbed oxygen from the air to form the dioxide. At 1,600° the oxygen thus absorbed was again set free, the monoxide being regenerated. In later methods the temperature was maintained constant at about 1,200° F, and change of pressure was relied upon for determining the respective phases of oxidation and deoxidation. The purity obtainable, however, was not more than 94%.

In 1902 Linde applied the process of rectification to liquid air and was able to extract oxygen of 98·5% purity in economical yield. Air is freed of its carbon dioxide, compressed, cooled and then expanded, either in an engine doing external work or merely through a valve to perform internal molecular work; in both cases heat is lost and the temperature further lowered. This cooling effect is made cumulative by means of heat interchangers, tubular metal devices by which the cold gases after expansion are made to travel in indirect contact with and in counter-current to the incoming uncooled compressed air, so that the latter becomes continually colder at the point of expansion, until a limit is set by liquefaction. The liquid so produced is made to flow down a rectification column, fitted with numerous plates fashioned to ensure its intimate contact with ascending gas, which is produced at the base of the column by evaporating the liquid as it arrives there. When equilibrium is attained, almost pure oxygen can be drawn from the bottom of the column in gaseous or liquid form. Improvements in construction introduced in 1926 enable the separation of the nitrogen and oxygen of air to be effected almost completely, the oxygen purity being 99·5%, and the nitrogen over 99%.

Oxygen is also a by-product in hydrogen manufacture by the electrolysis of water. The much greater power consumption, however, prevents this process competing with the liquid-air process for oxygen production only. The gas is supplied in steel cylinders at a pressure of 120–150 atmospheres. During 1926 the world's production of oxygen, in cylinders, was about 5,000 million cubic feet. The estimation of oxygen in a gas is most conveniently made by means of an alkaline solution of pyrogallol, by metallic copper in conjunction with an ammoniacal solution of ammonium carbonate, by sticks of phosphorus, or by a weakly alkaline solution of sodium hydrosulphite.

Oxygen condenses to a pale blue magnetic liquid, boiling at −182.97° C. By rapid evaporation and consequent cooling, or by cooling in liquid hydrogen, oxygen forms a bluish-white solid, melting at −219° C. When gaseous oxygen is acted on by the silent electric discharge, an unstable modification, ozone (*q.v.*) O_3 is produced.

Uses.—Most of the oxygen is employed in industry for the fusion welding of metals, *e.g.*, steel, cast iron, aluminium, lead, and for the cutting of steel. Gas welding is generally accomplished by the aid of the oxy-acetylene flame, the two gases being supplied to a blowpipe wherein they are thoroughly mixed before combustion. In practice a little more oxygen than acetylene is used, and the resulting flame has an inner white core with a temperature above 4,000° C; it is quickly able to reduce these metals to the molten state locally, where two edges are to be joined. For metal cutting, a separate jet of "cutting" oxygen is provided in a similar blowpipe, either in the centre of the heating jet or behind it. As a rule, the melting point of an oxide is higher than that of the metal from which it is derived; but the fusion point of industrial iron varies between 1,400–1,500° C, and the mixture of iron oxides fuses at about 1,350° C. In the cutting the oxides of iron are formed and blown away in the molten state before the unoxidized iron reaches its melting point, the necessary temperature being maintained chiefly by the heat of combustion itself, but to a less extent by an independent heating jet. When the cutting blowpipe is moved mechanically, and therefore regularly, over the metal a remarkably smooth regular cut is obtained, even through metal 17in. thick.

Oxygen is widely used in medical practice, inhalation being of service in cases of pneumonia, heart complaints, etc.; also in cases of gas poisoning, especially by carbon monoxide. It is used with nitrous oxide by anaesthetists.

Liquid oxygen has considerable industrial applications. If a rod of hard gas-carbon be heated to redness at one end and then immersed in liquid oxygen, it burns in the liquid with intense evolution of light and heat, the carbon dioxide resulting being frozen and retained as a white solid in the liquid. If the carbon is presented to the oxygen in a porous form, *e.g.*, wood charcoal, lampblack, soot, cork meal, sawdust, or wood pulp, the mixture forms a powerful explosive, more than twice as effective as blasting gelatine. It is so remarkably effective because the oxygen is free, and not chemically combined with other elements as in explosives like gunpowder or nitro-compounds, the explosion being an instantaneous oxidation of carbon, hydrogen or other elements. The materials are formed into cartridges in a paper wrapping; these may be 8in. long and 1½in. in diameter. They are thoroughly soaked in liquid oxygen and placed in the bore hole, and, after tamping, fired electrically or by fuse. This explosive has the great advantage that it automatically becomes dead in a short time if not fired, owing to the evaporation of the oxygen. It is exceptionally suitable for use in iron mines and in tunnelling, as it gives rise to no harmful gases.

The highly volatile liquid is transported in double-walled spherical vessels, made of spun copper with long, narrow necks. A good vacuum is created mechanically between the walls. When the excessively cold liquid oxygen is introduced into the vessel, activated charcoal (*q.v.*), placed in the vacuous space and in contact with the inner sphere, becomes cooled, and then possesses the remarkable property of absorbing the residual gas and converting the vacuum to one of an exceedingly high order (a few millionths of a mm. of mercury). This vacuum, coupled with the highly polished metal surfaces, prevents the ingress of heat

to a large extent. A 25-l. container (the usual size) loses by evaporation only 5% of its full liquid charge per day. The liquid is poured from them into smaller dipping flasks, of similar construction but cylindrical in shape with open top, so that the cartridges can be readily inserted and withdrawn. (For oxygen in relation to muscular contraction *see* MUSCLE AND MUSCULAR EXERCISE.)

OXYHYDROGEN FLAME, the flame attending the combustion of hydrogen and oxygen, and characterized by a very high temperature. (*See* FLAME.)

OYAMA, IWAO (1842–1916), Japanese marshal and statesman, raised in the peerage from count to marquess after the Chino-Japanese War (1894–95) and to prince after the Russo-Japanese War (1904–05). Son of a *samurai* of the Satsuma clan, he fought under Saigo Takamori at the time of the Restoration but against him in the Satsuma rebellion of 1877. He was sent twice to Europe to study military affairs while still a young officer; he was minister of war in 1880 and in 1885, and chief of the general staff in 1882, proceeding to Europe for the third time the following year. During the Chinese war he commanded the second army, which captured Port Arthur and Wei-hai-wei. In the Russian war he was commander in chief in Manchuria, and his name is associated with the battles of Liao-Yang, the Sha-ho and Mukden. After Mukden he was hailed in the British press as the equal of Marlborough and Wellington. He received the Order of Merit from King Edward VII in 1906.

OYER AND TERMINER, the Anglo-French name, meaning "to hear and determine," for one of the commissions by which a judge of assize sits (*see* ASSIZE). By the commission of oyer and terminer the commissioners (in practice the judges of assize, though other persons are named with them in the commission) are commanded to make diligent inquiry into all treasons, felonies and misdemeanours whatever committed in the counties specified in the commission, and to hear and determine the same according to law. By the Treason act of 1708 the crown may issue commissions of oyer and terminer in Scotland for the trial of treason and misprision of treason.

In the United States oyer and terminer is the name given to courts of criminal jurisdiction in some states; *e.g.*, New York, New Jersey, Pennsylvania and Georgia.

OYSTER. Oysters belong to a large class of molluscs called by Georges Cuvier "Bivalvia" because all members of this group have a two-valved shell which encloses a soft body. The class was later renamed Pelecypoda, which means that its members have a hatchet-shaped foot, and Lamellibranchia, *i.e.*, with platelike gills. In the course of evolution, oysters became sedentary and lost the foot, which is, however, present in their larvae.

The distribution of oysters is limited by the latitudes 64° N. and 44° S. Within this broad belt they occur in shallow inshore waters of all the continents.

Science recognizes about 100 species of living oysters and more than 500 fossil ones. Shape, size and sculpture of the oyster shell varies with the environment. Classification, based on these characters is therefore unreliable. There are two distinct groups of edible oysters: (1) the round and flat ones such as *Ostrea edulis* (Europe) and *O. lurida* (Pacific coast of North America); and (2) the long, cuplike species represented by *O. virginica* (Atlantic coast of U.S.), *O. gigas* (Japan), *O. commercialis* (Australia), *O. cucullata* (India), *O. chilensis* (Pacific coast of Central and South America) and *O. angulata* (Portugal and France). Since the two groups differ also in several anatomical and biological characteristics, the division of the genus *Ostrea* into two separate genera is justified. Various names, such as *Gryphaea, Saxostrea* and *Crassostrea,* proposed for the cuplike species did not receive general recognition. To eliminate the confusion, the International Commission on Zoological Nomenclature was requested to consider the matter. The name *Ostrea* is used in this article in a broad sense to include all species of edible oysters.

Structure and Functions of the Oyster Body.—The body of the American oyster rests on the left cuplike side. The right (upper) valve is usually flat. The narrow part of the shell marks the anterior end; the posterior end is broad and rounded. The valves are held together at a narrow hinge by an elastic ligament: They consist of layers of organic substance, conchiolin, impregnated with calcium carbonate and small quantities of other mineral salts secreted by the mantle, a soft membrane underlying the shell. The two flaps of the mantle, joined together on the dorsal side, embrace the body but leave the ventral edges free. Two rows of tentacles along each free border of the mantle guard the body. Mechanical disturbance, change in illumination or presence of irritating substances are sensed by the tentacles; the stimulus is conveyed through the nerves of the mantle to the muscle which closes the shell.

The majority of bivalves have two adductor muscles, anterior and posterior. Both of them are present in the larval oyster but only the posterior muscle remains in the adult. In many species the place of attachment of the adductor to the shell is dark-coloured. The muscle consists of a relatively small posterior part which is crescent shaped, white and opaque, and of the larger and translucent anterior part. The latter is made of striated fibres which contract more rapidly than the nonstriated fibres of the opaque part. The primary function of the nonstriated portion of the muscle is to keep the valves in any position to which they are brought by the contraction of the other part. The maintenance of the muscle tonus at any level of contraction requires no additional energy. This ability is attributed to the so-called catch mechanism of the adductor. When the muscle relaxes, the spring-like action of the elastic ligament forces the valves apart and the shell opens. The oyster has no means of attacking other animals and is able to protect itself only by closing the valves tightly and remaining hermetically sealed. Observations show that in the presence of harmful substances in the water those oysters which remain closed for a longer time survive better than those which open more frequently. The ability of all edible oysters to survive after being taken out of water is due to the catch mechanism of their adductor muscle. *O. virginica* may remain in good condition for about four months if kept in air at a temperature a few degrees above freezing. Warming, shaking, or rough handling causes the adductor to relax; the valves gap, the water retained inside the shell is lost and the oyster soon dies. Young *O. gigas*, taken out of water survive for three weeks at about 44.6° F. but remain alive only seven days at 65.3° F. One Australian oyster, *O. commercialis,* was reported to survive in the laboratory for six weeks out of water.

The power of the adductor muscle varies with the size and condition of the oyster. Laboratory experiments show that continuous pull equal to 22 lb. applied to the shell would fatigue the muscle of an adult American or Japanese oyster in less than an hour, but at least 17 days are needed to attain the same effect with the pulling force of 2.2 lb. A force of from 26 to 33 lb. is required to tear off the muscle of these oysters.

A pair of gills or branchiae are located under the mantle on the ventral side of the oyster. They are attached by their bases to the visceral mass, while their distal edges are free. Each gill consists of two plates (lamellae), V-shaped in a cross section. Space between the plates is called the interlamellar cavity. In a cross section of the body each gill appears as a W joined by the right and left limbs. Each gill plate is formed by many long and tubular filaments arranged in a series of folds or plicae which give the gill a pleated appearance. The filaments are kept together by a series of horizontal shelves which form interfilamentar junctions. The outer and inner lamellae of each plate are joined together by partitions (septae) which divide the interlamellar cavity into a series of water channels opening into a wide passage known as the suprabranchial chamber. The latter leads to the

cloaca through which the water is discharged to the outside. Free spaces between the filaments form oval-shaped openings, ostia, surrounded by powerful cilia which beat inward and force the water to enter the gill. Filaments are supported by an inside framework of chitinous rods; they contain blood vessels, muscle fibres, connective tissue, and nerves. The surface of the gill is covered with ciliated epithelium and mucous cells. The entire gill can be compared to a folded sieve through which the water is strained. Particles that settle on its surface are pushed by the cilia toward the edges of the lamellae where they enter the grooves and are transported toward the mouth.

The rate of pumping of water or ventilation of the gill can be accurately measured and recorded by the methods developed in U.S. laboratories. It depends on the size of the oyster, its condition and the temperature of the water. Large *O. virginica* were reported to pump as much as 35 l. per hour at temperatures of 71.6°–78.8° F.; the average rate at this temperature is about 15–16 l. With the onset of the cold season the pumping slows down and ceases at about 42.8° F.

Oxygen consumption by *O. virginica* kept at 77° F. is low; in an oyster 10 cm. long, it varies from 2 to 6 ml. of O_2 per hour. The food consists of minute algae and other micro-organisms strained from water and entangled in the mucus secreted by the gills. In feeding, the oyster discriminates between different types of food and selectively rejects the micro-organisms of unsuitable size or shape and those otherwise incompatible. The mechanism of selection is not completely understood.

Gills play an important role in the female spawning of *O. virginica*, *O. gigas*, and other cuplike oysters. Violent shell movements, which accompany female spawning, force the eggs, discharged from the ovary, to pass through the channels of the gill and ostia and accumulate in the mantle cavity. Ensuing sharp movements of the valves eject and disperse them in the water. In this way the chance for fertilization of eggs is greatly enhanced.

The alimentary canal begins at the mouth located on the ventral side at the anterior end of the body. Four triangular labial palps, two on each side, guard the mouth's opening. Their inner surfaces are covered with ciliated grooves and ridges. The function of the palps is to receive and sort out the food before it is ingested.

A narrow oesophagus opens into the stomach, a large, saclike structure with several pouches or outgrowths protruding from its sides. A finger-shaped posterior outgrowth contains crystalline style, a gelatinous rod about ½ in. long with a broad head projecting into the stomach. The crystalline style is not a permanent structure; it is always present in the actively feeding oysters but disappears shortly after their removal from water. The style rotates in its sack, mixing and grinding small food particles caught between its head and the gastric shield—a cuticular structure which lines the left side of the inner wall of the stomach. The style contains amylase, the enzyme which digests starch and glycogen, and several oxidases.

A short mid-gut leads from the stomach into the intestine; after making a forward loop, it continues backward into the rectum which opens into the suprabranchial chamber. Faeces discharged through a narrow anus are washed away by the outgoing current running through the cloaca. Time needed for food to pass through the entire alimentary canal of an adult *O. virginica* varies from 90 to 150 min. (at 68° F.).

A large brownish mass of digestive gland surrounds the stomach. It consists of numerous blind tubules (diverticula) kept together by connective tissue and lined by irregularly shaped epithelial cells.

Blood cells (phagocytes), always present in the tubules, engulf the food and digest it inside their bodies. Proteolytic enzyme and lipase have been extracted from digestive organs of oysters, but the question of whether these enzymes are secreted by the gland itself or are liberated from the phagocytes has not been settled.

The circulatory system consists of the heart, arteries, sinuses and veins. The heart has one ventrical and two auricles. The rate of pulsation is irregular, varying in *O. virginica* from 15 to 24 beats per minute at 64.4°–68° F. and decreasing with the drop of temperature. When the oyster closes its shell, the heart beat slows to two or three times per minute regardless of temperature. Through the arteries blood enters the irregular spaces in the tissues (sinuses) from which it flows into afferent veins and back to the heart. The blood is colourless. In *O. virginica*, it contains no haemocyanin or other blood pigment. The blood cells (amoebocytes and phagocytes) are capable of amoeboid movement and often aggregate on the outer surfaces of gills and mantle (diapedesis) and are discarded. One pair of visceral ganglia and a smaller pair of cerebral ganglia, with the connecting commissures and branches, constitute the nervous system. A large circumpallial nerve runs along the free edge of the mantle.

The excretory system consists of a pair of nephridia situated close to the adductor muscle and to the pericardium with which they communicate. They open into the suprabranchial chamber.

The sex organs (gonads) consist of many branching follicles forming a continuous creamy layer around the visceral mass. Each follicle is lined with germinal epithelium from which the sex cells develop. The degree of gonad development varies greatly, depending on the environment. Sexes in the oyster are not stable, and the changes of sex occur in all the species studied. In flat oysters of *O. edulis* type this change is rapid, the sperm beginning to develop a few days after the egg spawning. In *O. virginica* and other species of cuplike oysters the change of sex in either direction takes place during the winter resting phase. Observations conducted by Paul S. Galtsoff showed that in New England waters about 10% of adult oysters change their sex annually. Young *O. virginica* are predominantly males, but toward the end of the first year some of them change into females and a 1:1 ratio is established. Flat oysters of edulis type are larviporous, *i.e.*, the eggs are fertilized and develop in the mantle cavity and larvae are discharged at the advanced stage of development. In oviporous oysters (*O. virginica*, *O. gigas*, *O. commercialis* and others) eggs are dispersed in the water and are fertilized outside the organism. The larval period of *O. virginica* lasts from 14 to 23 days.

Chemical Composition.—The meat of the oyster consists of protein (8%–11%), carbohydrates (3.7%–9.6%), glycogen (0.4%–9.5%), fat (1.2%–2.5%), mineral salts (ash, 0.9%–3.0%) and large quantities of water (76%–89%). The following inorganic constituents are usually present: sodium, potassium, calcium, magnesium, chlorine, bromine, phosphorus and sulphur. Many of the heavy metals such as iron, copper, zinc, manganese and iodine are always present in variable quantities, and oysters grown in water contaminated by industrial wastes may accumulate large amounts of iron and copper and appreciable quantities of arsenic and lead. Excessive accumulation of copper produces a green discoloration and renders them unpalatable. The green colour of the European oyster, however, is caused by the absorption of a bluish-green pigment of a diatom, Nitszchia, which abounds in oyster grounds and is eaten by the oyster. Green oysters of the western coast of France are highly esteemed for their flavour.

The chemical composition of the meat changes from season to season and varies somewhat in oysters from different localities. Oysters may be eaten at any season of the year. The well-known "r" rule (that oysters should be eaten only during months in which the letter "r" occurs) probably originated from the observations that during the summer oysters are watery and contain but little glycogen. They can be eaten, however, without any danger to human health. Oyster meat is a low source of energy; an average serving of six raw *O. virginica* yields only about 60 calories.

Parasites and Commensals.—Like any other animals oysters harbour many parasites. Cysts of Nematopsis, a harmless sporozoan, are frequently found in the mantle, gills and other organs of *O. virginica* from southern latitudes. More serious are the infestations by *Dermocystidium marinum*, a funguslike microorganism which attacks the intestinal epithelium and produces abscesses in the tissues. Trematode worms, *Bucephalus haimeanus* and *B. cucullus*, infest oysters of various regions. The cercaria of these species are found in the visceral mass and gonads which they destroy. A parasitic copepod, *Mytilicola orientalis*, sometimes attacks *O. lurida* of the Pacific coast without causing serious injury to the host. The common oyster or pea crab, *Pinnotheres*

ostreum, for a long time considered a harmless commensal living on the gills of *O. virginica,* may inflict serious damage to the oyster and even cause its death. Many other invertebrates such as several species of boring sponge (*Cliona*) and boring clam (*Martesia*) damage the oyster shell and are thus injurious. Mud worms, *Polydora websteri* and *P. ligni,* settle on the inner side of the shell, collect mud and cause the formation of mud blisters. The slipper shell, *Crepidula fornicata,* settles sometimes in an incredibly large number on living oysters and becomes a great nuisance to oyster growers. Many Bryozoa, barnacles, ascidians and other invertebrates grow on oyster shells and occupy all the space that could have been available for the attachment of oyster larvae. *Eliminius modestus,* a barnacle incidentally introduced to British waters from the southern hemisphere, is particularly troublesome in this respect.

Predators.—Among the enemies preying on oysters the most dangerous are the various species of snails—*Urosalpinx cinerea, Tritonalia japonica, Thais heamastoma,* several species of *Busycon* and many others. They bore the shell of the oyster by their rasp-like radula and after reaching the meat devour it. Starfishes, particularly *Asterias forbesi* of New England waters, destroy millions of oysters every year. All these enemies, if not controlled, may completely devastate oyster populations. Among the fishes, the drum fish and skates frequently attack the oyster grounds. Control of these predators is possible, but difficult and expensive.

Pollution and Sanitary Control.—The discharge of industrial wastes into coastal waters often causes the destruction of oysters. In case of gross pollution, a large percentage of oysters may be killed outright; more often, however, the toxic substances coming from various establishments are so diluted by sea water that their deleterious effect is not immediately apparent. Under these conditions the oyster population may continue to live, but the growth of the oysters is retarded, they fail to fatten, become watery, and cease to propagate. Such changes may be observed in many areas affected by the pollution from pulp mills, oil fields and various industrial plants.

The discharge of untreated domestic sewage into natural waters rarely kills the oysters, but it renders them unmarketable. Sanitary regulations of many countries prohibit the taking of shellfish from waters which do not conform to the established standards of purity. The suitability of grounds for harvesting shellfish for human consumption is determined by a bacteriological examination of water. No shellfish is permitted to be taken from any area which contains more than 70 *Escherichia coli* in each 100 cu.cm. sample of water. This harmless bacterium flourishes in human intestines and is therefore a reliable indicator of pollution. Oysters from moderately polluted areas may be purified by chlorination, a process used in the U.S. and England. It consists in washing and disinfecting the outside surfaces of shells with chlorinated sea water, then placing the oysters for self-purification in sterile water containing no residual chlorine. The entire procedure requires from 24 to 48 hr.

Oyster Farming.—The origin of oyster culture or oyster farming is shrouded in antiquity. It probably started with the first attempts of primitive man to bring oysters from natural grounds and deposit them in a more accessible place near his habitation. Numerous shell heaps or kitchen middens in America and Europe show that tribes living near the sea used large quantities of shellfish for food. Long before the Christian era, the Chinese were cultivating oysters, and Romans successfully used artificial methods of growing them to satisfy the refined tastes of their epicures. During the 20th century the progress of biological research and food technology made possible rapid advancement in oyster farming. Many thousands of acres of barren sea bottom were converted into fertile farms under water; the quality of oysters was improved, new harvesting implements were invented, and reliable methods were developed for the preservation of oyster meat by canning, freezing and smoking. The annual world production of oysters by the 1950s approximated 1,600,000,000 lb.

Oyster farming consists of the following operations: (1) selection of suitable bottoms, clearing them from debris and predators and, if necessary, reinforcing them with shells or gravel; (2) planting sufficient number of adult oysters (spawners) for breeding; (3) scattering clean shells or collectors over the bottom or on tidal flats for the attachment of oyster larvae; (4) transplanting young oysters (seed) to growing and maturing grounds; (5) protecting the oysters against predators; and (6) harvesting. Grounds upon which larval oysters set in great abundance may not be suitable for the growth and fattening of market stock and vice versa. These peculiarities of oyster habitat must be studied and determined by field tests.

A crucial problem of oyster farming is the scarcity of seed oysters. In New Jersey, Virginia, Louisiana and the majority of the southern U.S. states oystermen do not grow seed oysters but are permitted to take them from public grounds under the supervision of the respective state authorities. New England oyster growers obtain seed oysters from their own grounds or buy them from others. In the state of Washington the producers of the Pacific oyster depend on the import of large quantities of seed of *O. gigas* from Japan. In other states of the U.S., oyster farming is not practised, but wild oysters are harvested from public reefs which in general are depleted because of overfishing and insufficient attention. European oyster-growers developed elaborate methods of obtaining seed on tile or brush collectors set on tidal flats. In Japan young oysters are frequently collected on garlands of shells strung on wire and suspended from poles exposed at low water.

For successful production of seed oysters it is important to know in advance the expected time of spawning and setting. Several empirical methods of predicting time of setting have been suggested. For instance, in the Netherlands the breeding of *O. edulis* may be expected to begin when water temperatures reach 59° F. and the release of larvae to occur periodically in June and July, ten days after the full and new moon. No lunar periodicity in breeding was observed in *O. virginica* but spawning of this oyster in Long Island sound usually begins between June 1 and 8, and setting may be expected about 18 days later. Deviations from normal air temperatures through January-April along the Pacific coast of the U.S. determine the time of setting of the native oyster, *O. lurida.* Methods of prediction were still in the formative stage in the 1950s and required further studies.

Artificial Raising of Larvae.—Larvae of *O. virginica, O. gigas* and *O. edulis* have been artificially raised in laboratories. Fertilized eggs of the first two species may be obtained by stimulating spawning in ripe females by adding sperm to the water and increasing the temperature. In a few hours, fertilized eggs develop into minute larvae which hatch out and swim in water. They are given food which consists of various small flagellates and unicellular algae. Cultures of these micro-organisms must be prepared in advance. Methods were still too laborious and expensive in the 1950s for practical application but were valuable for research.

Introduction of Foreign Species.—The American oyster, *O. virginica,* was planted in northern Europe, and unsuccessful attempts were made to establish this species in the waters of the Pacific coast. The Portuguese oyster, *O. angulata,* was accidentally introduced into the waters of the west coast of France and established itself in the area formerly occupied by *O. edulis.* Most spectacular was the case of the introduction of the Japanese species, *O. gigas,* into Puget sound and adjacent bays of the American coast where this oyster came to be successfully cultivated on a large scale. *O. gigas* was planted with fair success in Australia. In several instances an introduction of a foreign oyster was followed by a spread of new predators, which became destructive to local shellfish. The Japanese snail, *Tritonalia japonica,* brought into Puget sound with the first shipments of seed oysters from Japan, became a serious pest; and the American oyster drill, *Urosalpinx cionerea,* brought into England, became a serious menace to native *O. edulis.* Introduction of any foreign species of oyster must be carefully supervised to avoid such dangers.

Further physiological studies of food and feeding, fattening, respiration and growth are needed to place oyster farming on a sound scientific basis. These problems are studied in numerous oyster laboratories established for the purpose in western European countries, Japan, Australia, the Philippines, U.S. and Canada.

Pearls.—Edible oysters have no true pearls. Occasionally, round calcareous concretions may be found in their bodies; they have no lustre and are worthless. True pearl oysters of the genus *Pinctada* inhabit warm waters of the tropics. They differ from the edible oysters by the presence of byssus by which they attach themselves to the substratum, and by a number of other characters. The inside of their shell is lined with an iridescent nacreous layer absent in the shells of edible oysters.

OYSTER BAY, an unincorporated town of Nassau county, New York, U.S., on the north shore of Long Island, 28 mi. N.E. of the Brooklyn borough hall; served by the Long Island railroad. Pop. (1950) 5,215; (1940) 4,981. The village of Oyster Bay Cove had a population of 561 in 1950. There are many country estates in the vicinity. Oyster dredging, shipbuilding and manufacture of pharmaceuticals are the main industries. Oyster Bay was the home of Theodore Roosevelt, and his grave is on a hillside in Youngs Memorial cemetery. His home, "Sagamore Hill," stands on high ground, commanding delightful views. A seaside park, established as a memorial to Roosevelt, was opened in 1928. Oyster Bay harbour was explored by David P. de Vries in June 1639. A settlement from Lynn, Mass., was attempted in 1640 but was prevented by Gov. William Kieft, and for some years the territory around the harbour was claimed by both English and Dutch. The first permanent settlement was made by Peter Wright and others from Massachusetts in 1653. The harbour was a famous smuggling centre at the end of the 17th century.

OYSTER CATCHER or SEA PIE, a genus of wading birds, allied to the plovers. Conspicuous in both sexes by its black and white plumage and long red beak, the common oyster catcher (*Haematopus ostralegus*) is found on all coasts from Iceland to the Red sea. It feeds largely on marine worms, crustaceans and molluscs and is very wary. The hen lays three clay-coloured eggs blotched with black, usually on a shingle bank near the sea. The young are at first clothed in protectively coloured down and can run at once. Usually seen in pairs, oyster catchers sometimes congregate in large flocks. The courtship consists of a dance in which one or both birds run around piping. Sometimes this dance, losing its original significance, is performed as a social function by a number of birds.

The American species (*H. palliatus*) has a longer bill and less white on the back, and its call note differs from the musical "tu-lup" of the European bird. Various other species occur, some of which are entirely black.

OZANAM, ANTOINE FRÉDÉRIC (1813–1853), French scholar, was born at Milan on April 23, 1813. Antoine studied law at Paris, where he joined the Ampère family, Chateaubriand, Lacordaire, Montalembert and other leaders of the neo-Catholic movement. In conjunction with other young men he founded in May 1833 the celebrated charitable society of St. Vincent de Paul, which numbered before his death more than 2,000 members. In 1840 he became assistant professor of foreign literature at the Sorbonne and in 1844 full professor. He died at Marseilles on Sept. 8, 1853.

Ozanam was the leading historical and literary critic in the neo-Catholic movement in France during the first half of the 19th century. In contemporary movements he was an earnest advocate of Catholic democracy and socialism, and of the view that the church should adapt itself to the changed political conditions consequent to the Revolution.

His works were published in 11 volumes (Paris, 1862–65). They include *Deux chanceliers d'Angleterre, Bacon de Verulam et Saint Thomas de Cantorbéry* (Paris, 1836); *Dante et la philosophie catholique au XIIIème siècle* (Paris, 1839; 2nd ed., enlarged 1845); *Études germaniques*, 2 vol. (Paris, 1847–49), translated by A. C. Glyn as *History of Civilization in the Fifth Century* (London, 1868); *Documents inédits pour servir à l'histoire de l'Italie depuis le VIIIème siècle jusqu'au XIIIème* (Paris, 1850); *Les poètes franciscains en Italie au XIIIème siècle* (Paris, 1852). His letters were partially translated into English by A. Coates (London, 1886).

There are French lives of Ozanam by his brother, C. A. Ozanam (Paris, 1882), E. Humbert (Paris, 1880), C. Huit (Paris, 1882); M. de Lambel (Paris, 1887), L. Curnier (Paris, 1888), B. Faulquier (Paris, 1903). German lives by F. X. Karker (Paderborn, 1867) and E. Hardy (Mainz, 1878); English biography by K. O'Meara (Edinburgh, 1867; 2nd ed., London, 1878).

OZARK MOUNTAINS, more properly called highlands, are a group of moderate elevation lying in the five states of Missouri, Arkansas, Oklahoma, Kansas and Illinois. The total area is estimated at about 50,000 sq.mi., of which 33,000 are in Missouri. The highland is an elevated peneplain developed upon an asymmetrical dome whose apex is formed by igneous rocks outcropping in St. Francois and adjacent counties, in Missouri. The topography is dominantly of the ridge and valley type; most of the area has been sculptured out of limestone by streams with the abundant aid of underground solution. Except on the south and southeast the transition from highland to plain is very gradual. On the southeast there are high rocky bluffs that rise precipitously on the Mississippi river, and on the south the Boston mountains constitute a well-defined escarpment bordering on the Arkansas lowlands.

The Bostons of Arkansas, reaching elevations of about 2,300 ft. above sea level and the highest points in the Ozarks, have been sculptured into truly mountainous form by the Arkansas and White river systems. In Missouri there are several isolated knobs more than 1,700 ft. above sea level and one, Taum Sauk in Iron county, reaches an elevation of 1,772 ft. Turbulent streams flowing through deep-cut gorges, numerous caverns and springs, and well-wooded hills have made parts of the Ozarks attractive to summer visitors.

BIBLIOGRAPHY.—C. O. Souer, *The Geography of the Ozark Highlands of Missouri* (1920) and *Missouri Geological Survey*, vol. 8 (1894).

OZOKERITE or OZOCERITE may be designated as crude paraffin wax; it is found in many localities in varying degrees of purity and is named from Gr. ὄζειν, to emit odour, and κηρός, wax. Specimens have been obtained from Scotland, Northumberland and Wales as well as from about 30 other countries; it was formerly worked commercially in Utah, U.S., but these deposits are now worked out and the sole sources of commercial supply are in Galicia, at Boryslaw, Dzwiniacz and Starunia. While formerly as much as 20,000 tons were mined annually, the industry suffered from the competition of the greatly increased output of paraffin wax extracted from petroleum.

Ozokerite usually occurs in thin stringers and veins up to 1 ft. or so in thickness and is believed to have originated from the slow evaporation and oxidation of paraffin base petroleum. It is generally characterized by a higher melting point than the wax extracted from oils, though the paraffin "scale" deposited on the casing of certain oil wells in Trinidad was found to approximate closely in melting point to native ozokerite.

As found native, ozokerite ranges from a very soft wax to a black mass as hard as gypsum, the specific gravity varying from .85 to .95 and the melting point from 58° to 100° C. It is soluble in benzene, chloroform, carbon disulphide, etc. Galician ozokerite varies from light yellow to dark brown and usually melts at 62° C.

The ozokerite as mined is separated from its mineral impurities by boiling in water, when the wax rises to the surface. This crude

ozokerite is refined by treatment first with concentrated sulphuric acid and afterward with charcoal, the result being the ceresine or ceresin of commerce.

On distillation in a current of superheated steam, ozokerite yields a candlemaking material resembling the paraffin obtained from petroleum and shale oil but of higher melting point, and therefore of greater value if the candles made from it are to be used in hot climates. There are also obtained in the distillation light oils and a product resembling vaseline (*q.v.*). The residue in the stills consists of a hard, black, waxy substance, which in admixture with India rubber is employed under the name of Okonite as an electrical insulator. From the residue a form of the material known as heelball, used to impart a polished surface to the heels and soles of boots, is also manufactured. (J. R.)

OZONE is a gas which possesses the odour of chlorine or of moist phosphorus. It may be formed (1) by chemical action; (2) by electrolysis; (3) by the electrostatic field; (4) by ultraviolet rays; (5) by the radioactive elements; (6) by incandescent solids in air; (7) by the evaporation of water. Ozone has found quite general usage in many countries for the purification of water. At Philadelphia, Pa., a Vosmaer sterilizing tower 33 ft. high and 3 ft. in diameter has been shown to be capable of sterilizing 50,000 gal. of water per hour, using an ozone concentration of 1 g. per cubic metre; the plant supplying Paris deals with 24,000,000 gal. of water daily. Ozonized air has been utilized in food preservation, in surgery and therapeutics, in the bleaching and refining of oils, fats and varnishes. Its use in the fine chemical industry is of increasing importance. It is successfully employed in the manufacture of the flavouring material, vanillin, and the perfume, heliotropin.

Ozone, allotropic oxygen, chemical symbol O_3 (*see* POLYMORPHISM), is normally a colourless gas. In great thickness or under pressure the colour is blue. It is sparingly soluble in water (coefficient of solubility, 0.494); it has been liquefied to a deep blue liquid which is, however, dangerous to handle owing to its tendency to spontaneous explosion. Its boiling point is variously given as $-106°$ C. (Olszewski) and $-119°$ C. (Troost). Ozone is seven times as soluble in carbon tetrachloride as in water. Its solutions in this solvent and in acetic acid, acetic anhydride and chloroform are blue and fairly stable.

The simplest form of laboratory ozonizer was due to W. von Siemens (1857) and consists of two concentric glass tubes, the inner surface of the inner one and the outer surface of the outer one being coated with tin foil, and each of the tin-foil conductors being in metallic contact with the terminals of an electrical induction coil. A slow stream of dry oxygen is passed through the ozonizer and under the influence of the silent electric discharge the gas becomes charged with from 3% to 8% of ozone. Two types of ozonizers are employed on a large scale: those which have dielectrics in the path of the discharge—the Siemens and Halske, and Linder ozonizers—and those which have no dielectrics—the Schneller and the Vosmaer ozonizers. In the ozonair system a series of mica or micanite plates covered on both sides with a gauze of aluminum alloy are mounted side by side in a case into which air can be passed. Alternate plates are charged and earthed. The production is about 40–60 g. of ozone per kilowatt hour of energy at a concentration of 2 g. of ozone per cubic metre of air.

The first recorded observation on ozone was by Van Marum (1785) who found that electrified oxygen had a peculiar smell and tarnished mercury. In 1840 C. F. Schönbein noticed these properties in air subjected to the silent electric discharge, in oxygen generated by electrolysis of water and in the slow aerial combustion of phosphorus. He gave to the new gas the name ozone (ὄζειν, to smell). Ozone is evolved in many chemical reactions, as by the action of sulphuric acid on barium or sodium peroxide and on many per-salts (perborates, percarbonates, permanganates, persulphates, etc.). Fluorine decomposes water with the production of blue ozonized oxygen (H. Moissan, 1891). The least volatile portions of liquid ozone contain a denser gas of great chemical activity to which the name oxozone has been given with the molecular formula O_4. (C. D. Harries, 1911.) *See* OZONIDES.

The constitution of ozone as O_3 was demonstrated by T. Andrews and P. G. Tait (1860), J. L. Soret (1866–67) and B. Brodie (1872), by making use of the fact that certain essential oils (cinnamon and turpentine) absorb ozone without taking up any marked amount of oxygen. The loss in volume by absorption of the ozone from ozonized oxygen was twice that observed during the original ozonization of the gas. It was inferred from these experiments that three volumes of oxygen are condensed to produce two volumes of ozone. This conclusion was confirmed by comparing the rates of diffusion of ozone and chlorine, when the density of ozone calculated on the basis of T. Graham's law of gaseous diffusion was approximately 24 ($H=1$), agreeing with a molecular formula of O_3 (48).

Moeller, *Das Ozon* (Brunswick, 1921); J. W. Mellor, *A Comprehensive Treatise on Inorganic and Theoretical Chemistry,* vol. 1 (1922). (G. T. M.)

OZONIDES, in chemistry, combination of unsaturated compounds with ozone (*q.v.*), belonging to the class of organic peroxides. J. L. Soret observed the absorption of ozone by turpentine. Later on C. D. Harries (1903–15) found that all unsaturated organic compounds in inert solvents such as hexane, carbon tetrachloride or ethylacetate combine with ozone to form ozonides. Thus ethylene gives the ozonide $C_2H_4O_3$, cyclohexene the ozonide $C_6H_{10}O_3$ and benzene a triozonid $C_6H_6O_9$. Ozonides may be monomeric or polymeric. The former are liquids which often can be distilled or crystalline compounds; the polymeric ones are amorphous. The characteristic feature of a monomeric ozonide is a five-membered peroxide ring with acetalic properties (H. Staudinger) $>C\genfrac{\langle}{\rangle}{0pt}{}{OO}{O}C<$. A. Rieche proved this constitution by synthesis from bishydroxy-peroxides. The ozonides are compounds of various stability: Some types are highly explosive, others may rearrange spontaneously; nearly all are sensitive to dilute acids by which they are hydrolysed to aldehydes or ketones and hydrogen peroxide. Catalytic hydrogenation gives only aldehydes or ketones, whereas peracetic acid produces mainly acids as splitting products. All ozonides can be estimated by their action with potassium iodide, one mole liberating two atoms of iodine. The oxozonides, by-products of some ozonizations, were shown to be di- or polymeric aldehyde- or keto-peroxides. The ozonolysis (ozonization followed by hydrolysis or hydrogenolysis) is an important tool to elucidate the position of a double bond in unsaturated compounds such as caoutchouc, terpenes or oleic acid, and to synthesize rare aldehydes. (R. CE.)
